Detector Systems

ON UNITARY REPRESENTATIONS OF THE INHOMOGENEOUS LORENTZ GROUP*

By E. WIGNER

(Received December 22, 1937)

of the invariance of the transition probability we have

$$|\langle \varphi_l, \psi_l \rangle|^2 = |\langle \varphi_{l'}, \psi_{l'} \rangle|^2$$

and it can be shown⁴ that the aforementioned constants in the φ_l can be chosen in such a way that the φ_l are obtained from the φ_l by a linear unitary operation, depending, of course, on l and l'

$$\varphi_{l'} = D(l', l)\varphi_{l}.$$

By going over from a first system of reference l to a second $l' = L_1 l$ and then to a third $l'' = L_2 L_1 l$ or directly to the third $l'' = (L_1 L_1) l$, one must obtain—apart from the above mentioned constant—the same set of wave functions. Hence from

$$\varphi_{l''} = D(l'', l')D(l', l)\varphi_l$$

$$\varphi_{l''} = D(l'', l)\varphi_l$$

it follows

(3)
$$D(l'', l')D(l', l) = \omega D(l'', l)$$

D. Classification of unitary representations from the point of view of infinitesimal operators

E. Wigner:

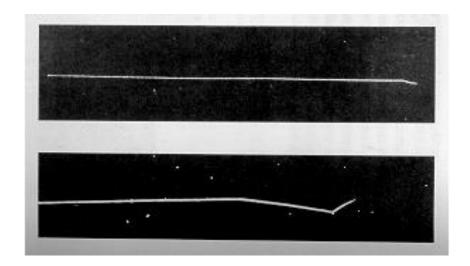

"A particle is an irreducible representation of the inhomogeneous Lorentz group"

Spin=0,1/2,1,3/2 ... Mass ≥ 0

Particle Detector

W. Riegler:

A particle detector is a classical device, that is collapsing wave functions of quantum mechanical states, which themselves are linear super positions of irreducible representations of the inhomogeneous Lorentz group (Poincare group).

Solvay Conference 1927, Einstein:

"A radioactive sample emits alpha particles in all directions; these are made visible by the method of the Wilson Cloud Chamber. Now, if one associates a spherical wave with each emission process, how can one understand that the track of each alpha particle appears as a (very nearly) straight line "

Born, Heisenberg:

"As soon as such an ionization is shown by the appearance of cloud droplets, in order to describe what happens afterwards one must reduce the wave packet in the immediate vicinity of the drops. One thus obtains a wave packet in the form of a ray, which corresponds to the corpuscular character of the phenomenon."

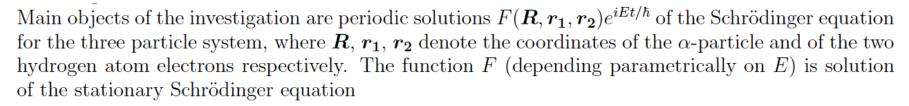

According to this reasoning the whole process is described in terms of the interaction of a quantum system (the alpha particle) with a classical measurement apparatus (the atoms of the vapour).

Nevill Mott (1929):

Assuming the atoms of the vapour also to be part of the quantum mechanical system, " ... it is a little difficult to picture how it is that an outgoing spherical wave can produce a straight track; we think intuitively that it should ionise atoms at random throughout space."

Mott considers and example with and alpha particle at the origin, one hydrogen atom at position $\mathbf{a_1}$ and another hydrogen atom at $\mathbf{a_2}$, and the two hydrogen atoms only having EM interaction with the alpha particle:

[Mo] Mott N.F., The wave mechanics of α-ray tracks. *Proc. R. Soc. Lond. A*, **126**, 79-84, 1929. Reprinted in: Wheeler J.A., Zurek W., *Quantum Theory and Measurement*, Princeton University Press, 1983.

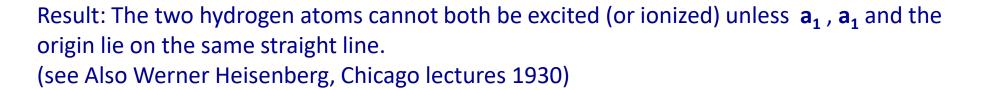

$$-\frac{\hbar^2}{2M}\Delta_R F + \left(-\frac{\hbar^2}{2m}\Delta_{r_1} - \frac{e^2}{|\boldsymbol{r_1} - \boldsymbol{a_1}|}\right) F + \left(-\frac{\hbar^2}{2m}\Delta_{r_2} - \frac{e^2}{|\boldsymbol{r_2} - \boldsymbol{a_2}|}\right) F$$

$$-\left(\frac{2e^2}{|\boldsymbol{R} - \boldsymbol{r_1}|} + \frac{2e^2}{|\boldsymbol{R} - \boldsymbol{r_2}|}\right) F = E F$$

$$(4.1)$$

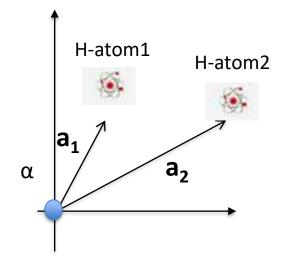

where Δ_x is the laplacian with respect to the coordinate x, M is the mass of the α -particle, m is the mass of the electron, -e is the charge of the electron so that 2e is the charge of the α -particle.

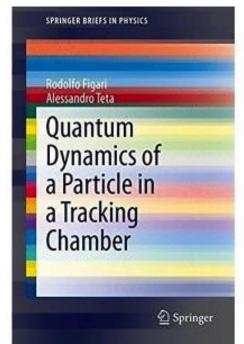

This example (i.e. moving the boundary between the quantum system and classical measurements device) is also used by S. Coleman in the lecture

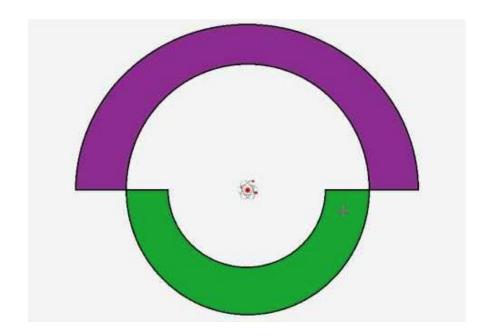

Quantum Mechanics in Your Face [1994] https://www.youtube.com/watch?v=EtyNMIXN-sw

Renninger's negative-result experiment (1953)

A radioactive atom (emitting and alpha particle) is placed in the center of a detector that consists of two hemispheres and that are 100% efficient to alpha particles.

Considering the second (purple) hemisphere to be very large, the absence of the a signal on the green detector after a given time will indicate that the alpha particle will hit the purple detector.

The QM analysis will come out right, with a given probability for the red or the green part to fire and zero probability that both fire.

The semi-classical analysis is however confusing:

The wave-function has collapsed although there was no measurement performed with the green detector? A non measurement collapses a wave-function?

W. Riegler:

"...a particle is an object that interacts with your detector such that you can follow it's track,

it interacts also in your readout electronics and will break it after some time,

and if you a silly enough to stand in an intense particle beam for some time you will be dead ..."

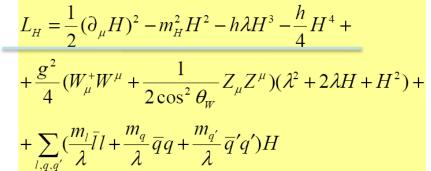

Elektro-Weak Lagrangian

$$L_{GSW} = L_{0} + L_{H} + \sum_{l} \left\{ \frac{g}{2} \overline{L}_{l} \gamma_{\mu} \overline{\tau} L_{l} \overline{A}^{\mu} + g' \left[\overline{R}_{l} \gamma_{\mu} R_{l} + \frac{1}{2} \overline{L}_{l} \gamma_{\mu} L_{l} \right] B^{\mu} \right\} +$$

$$+ \frac{g}{2} \sum_{q} \overline{L}_{q} \gamma_{\mu} \overline{\tau} L_{q} \overline{A}^{\mu} +$$

$$+ g' \left\{ \frac{1}{6} \sum_{q} \left[\overline{L}_{q} \gamma_{\mu} L_{q} + 4 \overline{R}_{q} \gamma_{\mu} R_{q} \right] + \frac{1}{3} \sum_{q'} \overline{R}_{q'} \gamma_{\mu} R_{q'} \right\} B^{\mu}$$

$$L_{I} = \frac{1}{2} (2) LD^{2} = 2 L^{2} L^{2} L^{2} L^{3} L^{3} L^{4} L^{4}$$

 $\Lambda^{o} \rightarrow p^{+} + \pi^{-}$

"If 1 is a Probon and 2 is a Pion the Mass of He V° particle is"

I Bechjiehor it the Expensed by looking of the spourfic Ionization (see loke)

Lifetime of a Particle → Exponential distribution

M-Lifetime

The muon (ony unlaste Porticle) Boesn't have on inner 'clock', i.e. nothing that tells it' age.

What is the probability P(t)dt that the muon will decay between time t and t+dt after starting to measure it – independently of how long it lived before ?

Probability p that it decays within the time interval dt after starting to measure = p=P(0) dt = c_1 dt.

Probability that is does NOT decay in n time intervals dt but the $(n+1)^{st}$ time interval = $(1-p)^n$ p \approx exp(-n p) p with p = c_1 dt.

n time intervals of dt means a time of $t = n dt \rightarrow$

Probability that the particle decays between time t and t+dt = $Exp(-c_1 t) c_1 dt = P(t) dt !$

The Probability that it Decays at time

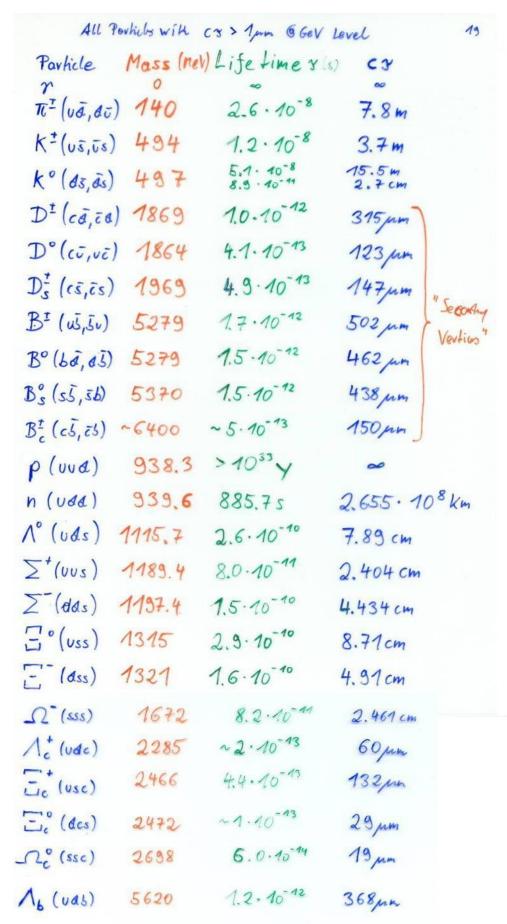

t after storing to measure it (instepesal of what
hoppard before) is
$$P(t) = \frac{1}{3}e^{-\frac{t}{3}}$$

ALEPH detector (LEP 1988 - 2000)

$Z \rightarrow e^+ e^-$

Two high momentum charged particles depositing energy in the Electro Magnetic Calorimeter

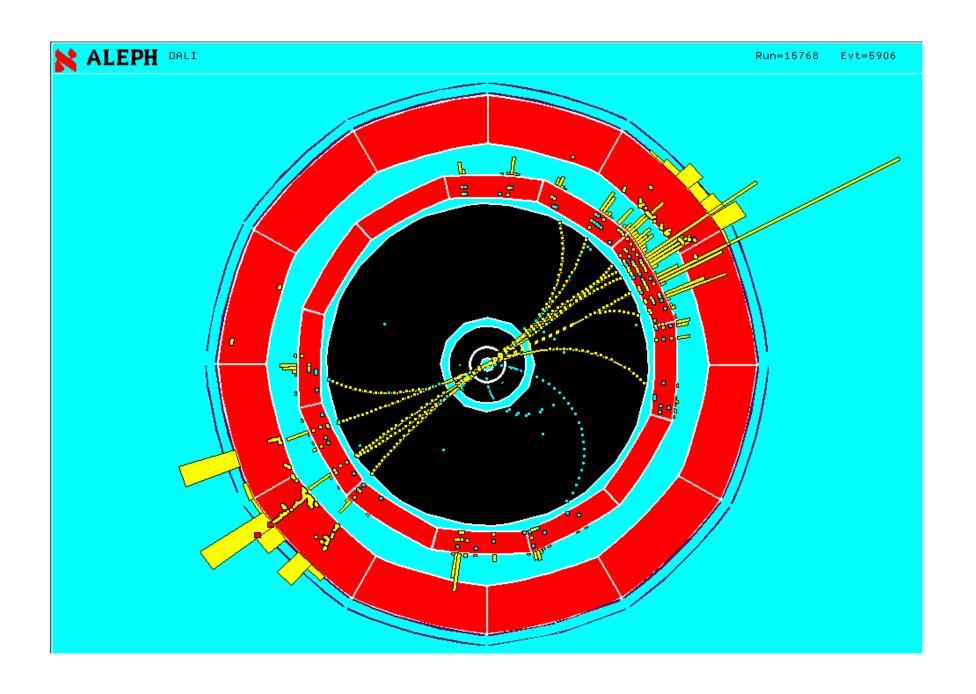

$Z \rightarrow \mu^+ \mu^-$

Two high momentum charged particles traversing all calorimeters and leaving a signal in the muon chambers.

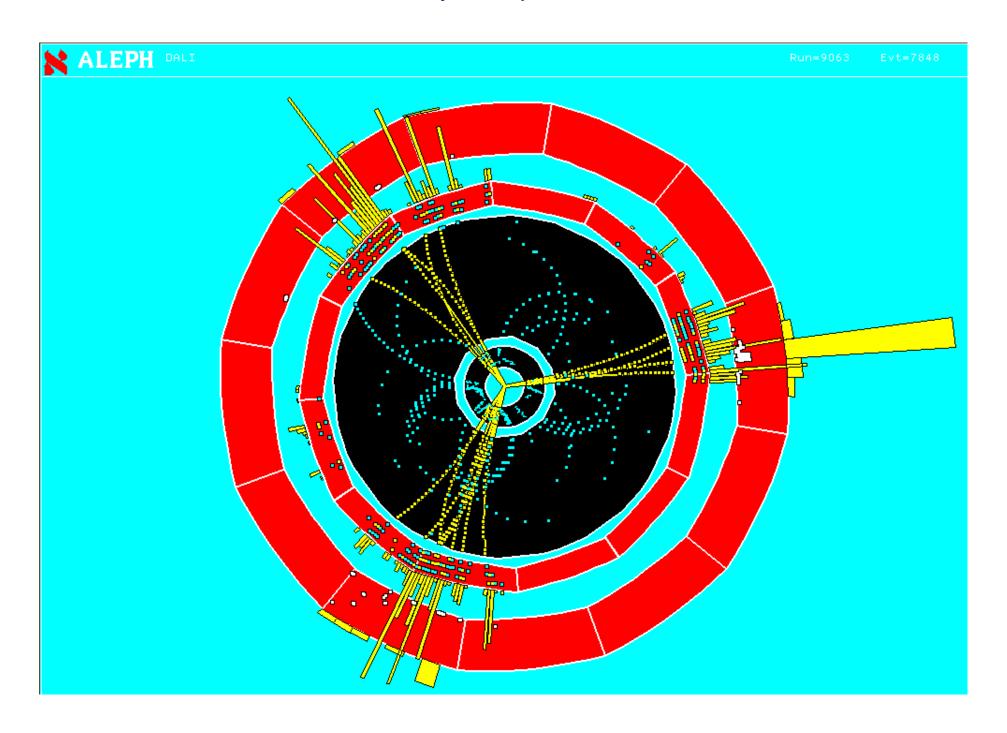

$Z \rightarrow q \overline{q}$

Two jets of particles

$Z \rightarrow q \overline{q} g$

Three jets of particles

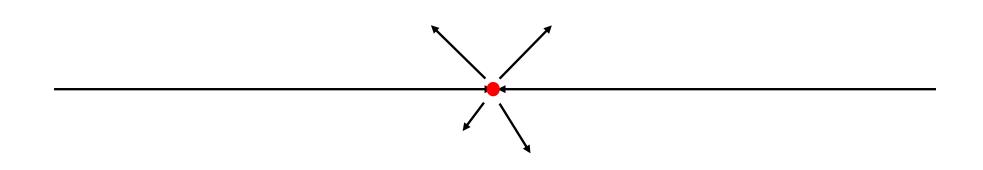

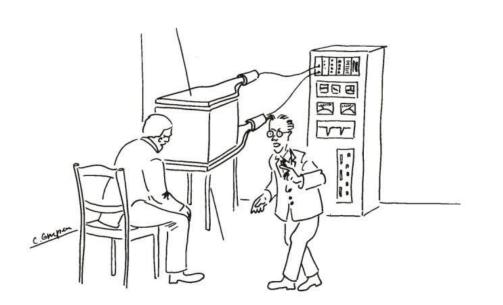

Interaction of Particles with Matter

Any device that is to detect a particle must interact with it in some way → almost ...

In many experiments neutrinos are measured by missing transverse momentum.

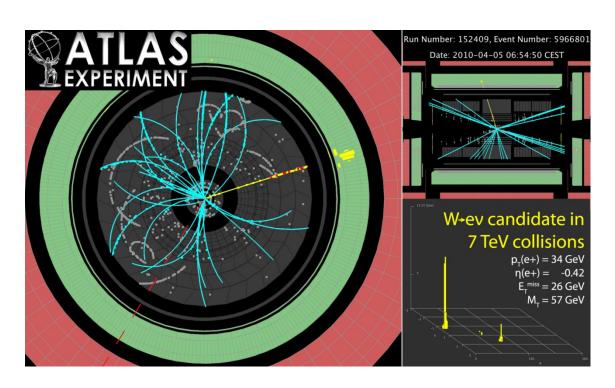

E.g. e^+e^- collider. $P_{tot}=0$, If the Σ p_i of all collision products is $\neq 0 \rightarrow$ neutrino escaped.

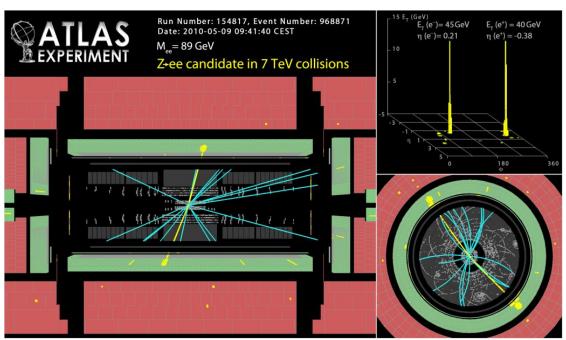

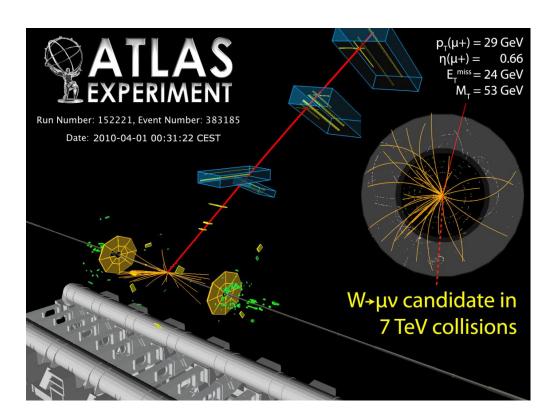

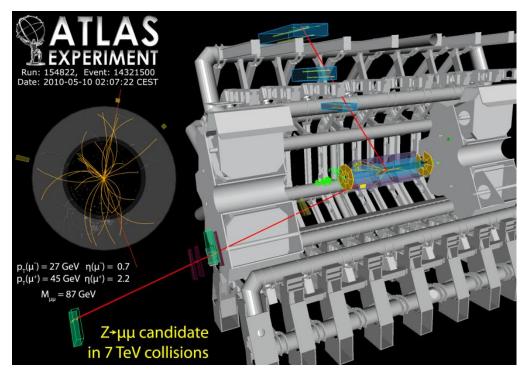

"Did you see it?"
"No nothing."
"Then it was a neutrino!"

2010 ATLAS W, Z candidates!

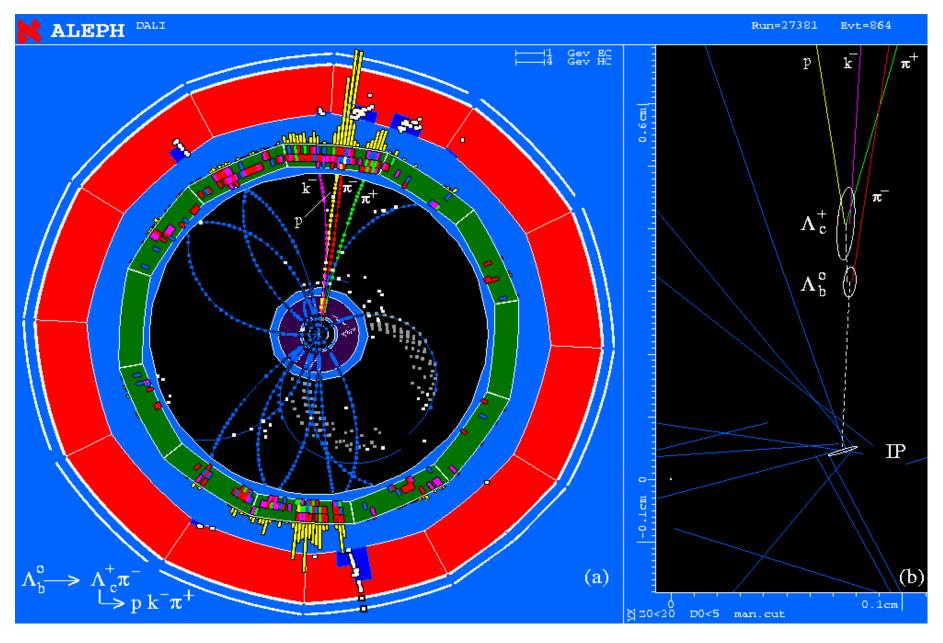

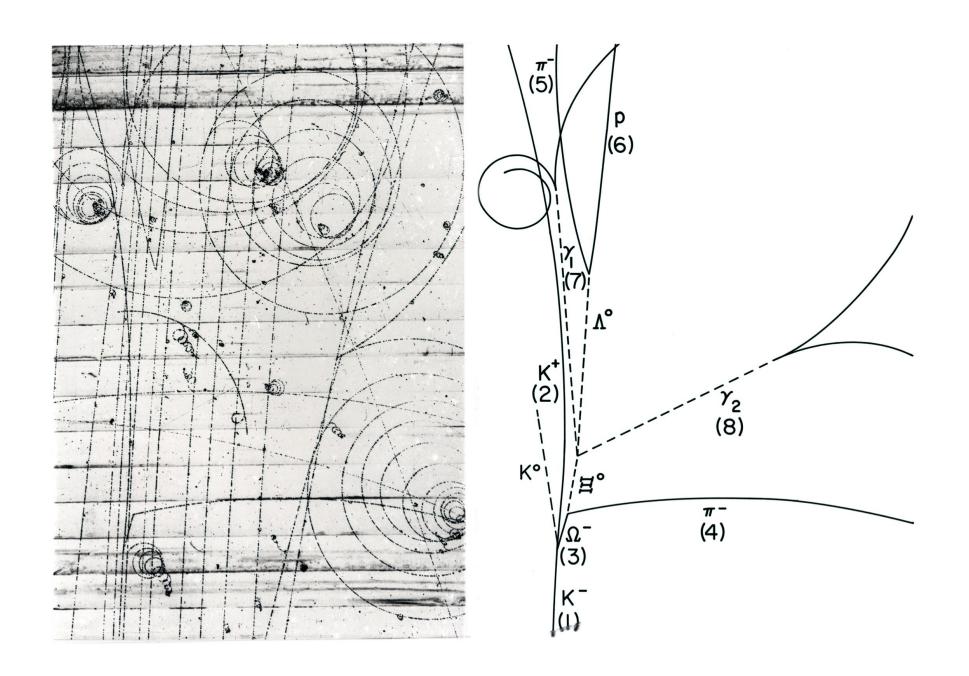

Two secondary vertices with characteristic decay particles giving invariant masses of known particles.

Bubble chamber like – a single event tells what is happening. Negligible background.

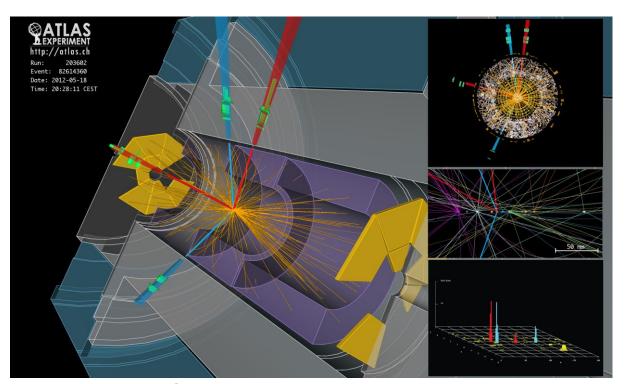

Discovery of 'new' Particles

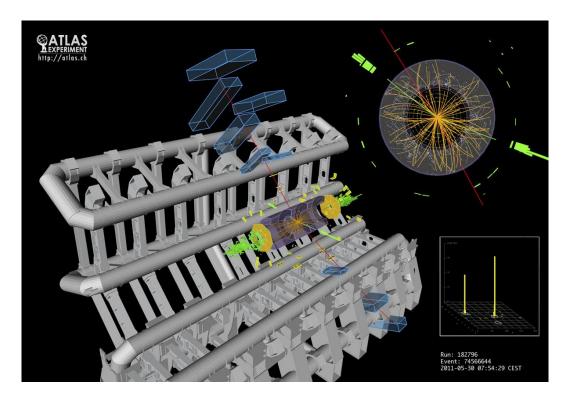

Discovery of Ω at the Brookhaven National Laboratory 80 inch hydrogen bubble chamber in 1964. Discovery claimed by a single event – 'background free'

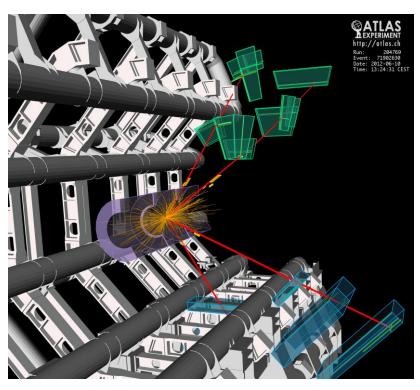

Candidate Higgs Events

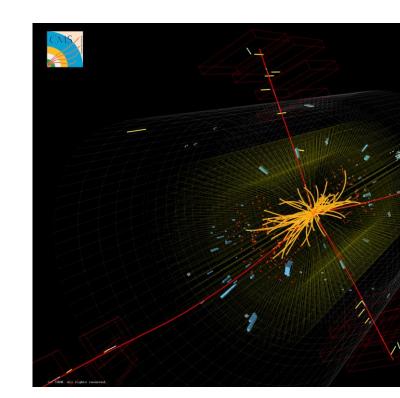

Candidate Higgs → 4e

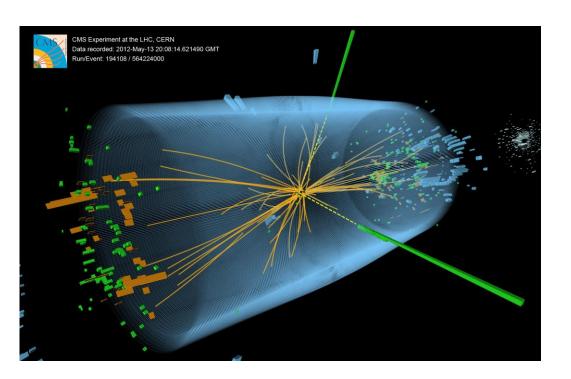

Candidate Higgs → 2µ2e

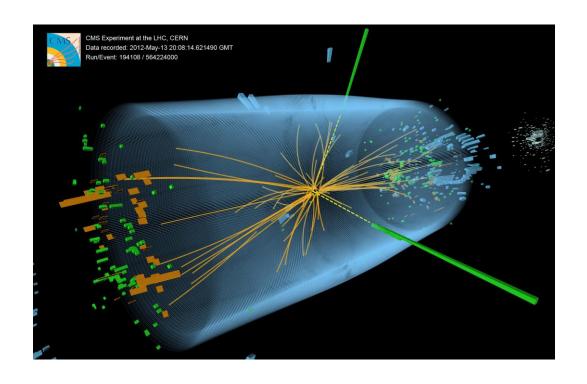

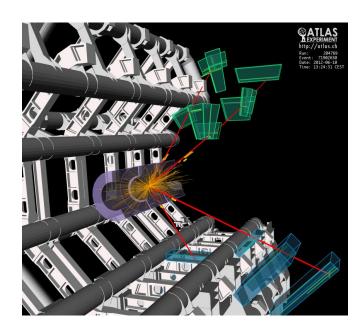

Candidate Higgs → 4µ

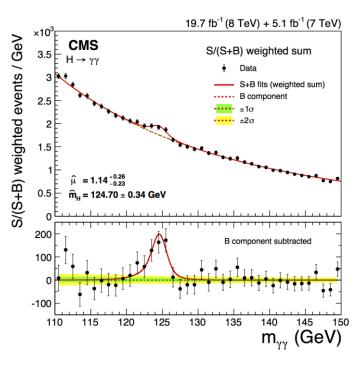

Candidate Higgs → 2 photons

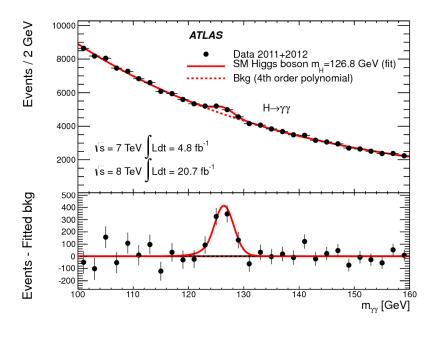

Signal and Background

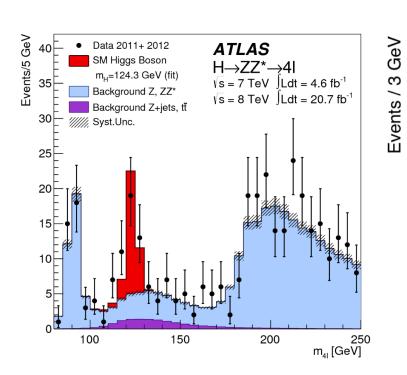

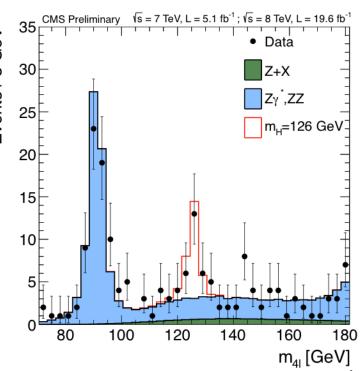

Particles are typically seen as an excess of events above an irreducible (i.e. indistinguishable) background.

Conclusion

Only a few of the numerous known particles have lifetimes that are long enough to leave tracks in a detector.

Most of the particles are measured though the decay products and their kinematic relations (invariant mass). Most particles are only seen as an excess over an irreducible background.

Some short lived particles (b,c –particles) reach lifetimes in the laboratory system that are sufficient to leave short tracks before decaying \rightarrow identification by measurement of short tracks.

In addition to this, detectors are built to measure the 8 particles.

$$e^{\pm}$$
, u^{\pm} , γ , π^{\pm} , K^{\bullet} , p^{\pm} , n

Their difference in mass, charge and interaction is the key to their identification.

Conclusion

A particle detector is an (almost) irreducible representation of the properties of these 8 particles

$$e^{\pm}, \mu^{t}, \gamma, \pi^{t}, K^{t}, K^{o}, p^{t}, n$$
