Discrete Gate Quantum Computing

Superconductor QCs

Qubit model:

$$|\psi\rangle = \cos \frac{\theta}{2} |0\rangle + e^{i\phi} \sin \frac{\theta}{2} |1\rangle$$

Advantages:

- Highly controllable qubits
- Universal computation

Disadvantages:

- Small number of qubits, not very fault tolerant

Single qubit gates:

$$U_3 |0\rangle \rightarrow \cos \frac{\theta}{2} |0\rangle + e^{i\phi} \sin \frac{\theta}{2} |1\rangle$$

Multi-qubit gates:

$$\begin{aligned} \text{CNOT } |00\rangle &\rightarrow |00\rangle, \text{CNOT } |10\rangle \rightarrow |11\rangle, \\ \text{CNOT } |01\rangle &\rightarrow |01\rangle, \text{CNOT } |11\rangle \rightarrow |10\rangle \end{aligned}$$

Event Generation - What's the
problem?

- **The Parton Shower**

The Parton Shower

Soft mode:

Interference effects only allow for partial factorisation

Leading contributions to the decay rate in the collinear limit are included in the soft limit

Collinear mode:

Successive decay steps factorise into independent quasi-classical steps

In this limit, the decay from high energy to low energy proceeds as a **colour-dipole cascade**.

This interpretation allows for straightforward interference patterns and momentum conservation

The Parton Shower - The Veto Algorithm

The choice of the variables ξ and t is known as the **phase space parameterisation**

Non-Emission Probability

$$\Delta(t_n, t) = \exp \left(- \int_t^{t_n} dt d\xi \frac{d\phi}{2\pi} C \frac{\alpha_s}{2\pi} \frac{2s_{ik}(t, \xi)}{s_{ij}(t, \xi) s_{jk}(t, \xi)} \right)$$

$$\mathcal{F}_n(\Phi_n, t_n, t_c; O) = \Delta(t_n, t_c) O(\Phi_n)$$

Master Equation

$$+ \int_{t_c}^{t_n} dt d\xi \frac{d\phi}{2\pi} C \frac{\alpha_s}{2\pi} \frac{2s_{ik}(t, \xi)}{s_{ij}(t, \xi) s_{jk}(t, \xi)} \Delta(t_n, t) \mathcal{F}_n(\Phi_{n+1}, t, t_c; O)$$

Inclusive Decay Probability

$$d\mathcal{P}(q(p_I)\bar{q}(p_K) \rightarrow q(p_i)g(p_j)\bar{q}(p_k)) \simeq \frac{ds_{ij}}{s_{IK}} \frac{ds_{jk}}{s_{IK}} C \frac{\alpha_s}{2\pi} \frac{2s_{IK}}{s_{ij}s_{jk}}$$

Current interpretations of the veto algorithm treat the phase space variables ξ and t as **continuous**

Discrete QCD - Abstracting the Parton Shower Method

1. Parameterise phase space in terms of gluon transverse momentum and rapidity:

$$k_{\perp}^2 = \frac{s_{ij}s_{jk}}{s_{IK}} \quad \text{and} \quad y = \frac{1}{2} \ln \left(\frac{s_{ij}}{s_{jk}} \right)$$

which leads to the inclusive probability:

$$d\mathcal{P} (q(p_I)\bar{q}(p_K) \rightarrow q(p_i)g(p_j)\bar{q}(p_k)) \simeq \frac{C\alpha_s}{\pi} d\kappa dy$$

where $\kappa = \ln \left(\frac{k_{\perp}^2}{\Lambda^2} \right)$ and Λ is an arbitrary mass scale

Due to the colour charge of emitted gluons, the rapidity span for subsequent dipole decays is increased. This is interpreted as **“folding out”**

Discrete QCD - Abstracting the Parton Shower Method

2. Neglect $g \rightarrow q\bar{q}$ splittings and examine transverse-momentum-dependent running coupling

$$\alpha_s(k_{\perp}^2) = \frac{12\pi}{33 - 2n_f} \frac{1}{\ln(k_{\perp}^2/\Lambda_{\text{QCD}}^2)}$$

leads to the inclusive probability

$$d\mathcal{P}(q(p_I)\bar{q}(p_K) \rightarrow q(p_i)g(p_j)\bar{q}(p_k)) \simeq \frac{d\kappa}{\kappa} \frac{dy}{\delta y_g} \quad \text{with} \quad \delta y_g = \frac{11}{6}$$

Interpreting the running coupling renormalisation group as a gain-loss equation:

Glucos within δy_g act coherently as one effective gluon

Discrete QCD - Abstracting the Parton Shower Method

2. Neglect $g \rightarrow q\bar{q}$ splittings and examine transverse-momentum-dependent running coupling

$$\alpha_s(k_{\perp}^2) = \frac{12\pi}{33 - 2n_f} \frac{1}{\ln(k_{\perp}^2 / \Lambda_{\text{QCD}}^2)} = \frac{\text{const.}}{\kappa}$$

leads to the inclusive probability

$$d\mathcal{P}(q(p_I)\bar{q}(p_K) \rightarrow q(p_i)g(p_j)\bar{q}(p_k)) \simeq \frac{d\kappa}{\kappa} \frac{dy}{\delta y_g} \quad \text{with} \quad \delta y_g = \frac{11}{6}$$

Interpreting the running coupling renormalisation group as a gain-loss equation:

Glucos within δy_g act coherently as one effective gluon

Discrete QCD - Abstracting the Parton Shower Method

Folding out extends the baseline of the triangle to positive y by $\frac{l}{2}$, where l is the height at which to emit effective gluons

A consequence of folding is that the κ axis is quantised into multiples of $2\delta y_g$

Each rapidity slice can be treated independently of any other slice. The exclusive rate probability takes the simple form:

$$\frac{d\kappa}{\kappa} \exp\left(-\int_{\kappa}^{\kappa_{max}} \frac{d\bar{\kappa}}{\bar{\kappa}}\right) = \frac{d\kappa}{\kappa_{max}}$$

Discrete QCD as a Quantum Walk

The **baseline** of the grove structure contains all kinematics information

For LEP data there are **24 unique grove structures** for $\Lambda_{\text{QCD}} \in [0.1, 1]$ GeV

The groves can be **constructed and enumerated** to achieve an **efficient** sampling algorithm for the dipole shower

Generating Scattering Events from Groves

Once the grove structure has been selected, event data can be synthesised in the following steps using the baseline:

1. Create the highest κ effective gluons first (i.e. go from top to bottom in phase space)
2. For each effective gluon j that has been emitted from a dipole IK , read off the values s_{ij} , s_{jk} and s_{IK} from the grove
3. Generate a uniformly distributed azimuthal decay angle ϕ , and then employ momentum mapping (here we have used [Phys. Rev. D 85, 014013 \(2012\), 1108.6172](#)) to produce post-branching momenta

The algorithm has been run on both the `ibm_qasm_simulator` and the `ibm_algiers 27` qubit device. A like-for-like classical implementation has been used as a comparison.

Discrete QCD as a Quantum Walk - Raw Grove Simulation

The algorithm has been run on the **IBM Falcon 5.1 Ir chip**

The figure shows the uncorrected performance of the **ibmq_algiers** device compared to a simulator

The 24 grove structures are generated for a $E_{CM} = 91.2$ GeV, corresponding to typical collisions at LEP.

Main source of error from CNOT errors from large amount of SWAPs

Track Finding via Associative Memory

A critical stage of event reconstruction and classification in modern colliders is the identification of **charged particle trajectories**

Highly **granular** detectors are used to efficiently measure the **position** of **charged particles** as they move through the detector

Classical techniques like **Associative Memory** have been shown to be **highly effective**, but **new approaches** are required as collider **energy and luminosity increase** to handle the growing number of **tracks and combinatorics**

Quantum Amplitude Amplification

The aim is to **identify** interesting states in a database $X = \{x_0, x_1, \dots, x_N\}$ with **interesting states** m_i encoded on a quantum device as $|s\rangle = \mathcal{A} |0\rangle^{\otimes n}$

Marking interesting states, $|m\rangle$ using the **oracle**

$$f(x) = \begin{cases} 1 & \text{if } x = m, \\ 0 & \text{otherwise.} \end{cases} \quad \longrightarrow \quad S_f |x\rangle = (-1)^{f(x)} |x\rangle$$

Amplify marked states using the diffusion operation:

$$D = \mathcal{A}^\dagger S_0 \mathcal{A}$$

Therefore, can iteratively apply the **Grover Iterator**:

$$Q = \mathcal{A}^\dagger S_0 \mathcal{A} S_f$$

Quantum Amplitude Amplification

$$|s'\rangle = \frac{1}{\sqrt{N-1}} \sum_{n=1}^{N-1} |n-1\rangle$$

The aim is to **identify** interesting states in a database $X = \{x_0, x_1, \dots, x_N\}$ with **interesting states** m_i encoded on a quantum device as $|s\rangle = \mathcal{A} |0\rangle^{\otimes n}$

Marking interesting states, $|m\rangle$ using the **oracle**

$$f(x) = \begin{cases} 1 & \text{if } x = m, \\ 0 & \text{otherwise.} \end{cases} \quad \longrightarrow \quad S_f |x\rangle = (-1)^{f(x)} |x\rangle$$

Amplify marked states using the diffusion operation:

$$D = \mathcal{A}^\dagger S_0 \mathcal{A}$$

Therefore, can iteratively apply the **Grover Iterator**:

$$Q = \mathcal{A}^\dagger S_0 \mathcal{A} S_f$$

Quantum Amplitude Amplification

The aim is to **identify** interesting states in a database $X = \{x_0, x_1, \dots, x_N\}$ with **interesting states** m_i encoded on a quantum device as $|s\rangle = \mathcal{A} |0\rangle^{\otimes n}$

Marking interesting states, $|m\rangle$ using the **oracle**

$$f(x) = \begin{cases} 1 & \text{if } x = m, \\ 0 & \text{otherwise.} \end{cases} \quad \longrightarrow \quad S_f |x\rangle = (-1)^{f(x)} |x\rangle$$

Amplify marked states using the diffusion operation:

$$D = \mathcal{A}^\dagger S_0 \mathcal{A}$$

Therefore, can iteratively apply the **Grover Iterator**:

$$Q = \mathcal{A}^\dagger S_0 \mathcal{A} S_f$$

Quantum Amplitude Amplification

The aim is to **identify** interesting states in a database $X = \{x_0, x_1, \dots, x_N\}$ with **interesting states** m_i encoded on a quantum device as $|s\rangle = \mathcal{A} |0\rangle^{\otimes n}$

Marking interesting states, $|m\rangle$ using the **oracle**

$$f(x) = \begin{cases} 1 & \text{if } x = m, \\ 0 & \text{otherwise.} \end{cases} \quad \longrightarrow \quad S_f|x\rangle = (-1)^{f(x)}|x\rangle$$

Amplify marked states using the diffusion operation:

$$D = \mathcal{A}^\dagger S_0 \mathcal{A}$$

Therefore, can iteratively apply the **Grover Iterator**:

$$Q = \mathcal{A}^\dagger S_0 \mathcal{A} S_f$$

Quantum Amplitude Amplification

The aim is to **identify** interesting states in a database $X = \{x_0, x_1, \dots, x_N\}$ with **interesting states** m_i encoded on a quantum device as $|s\rangle = \mathcal{A} |0\rangle^{\otimes n}$

Marking interesting states, $|m\rangle$ using the **oracle**

$$f(x) = \begin{cases} 1 & \text{if } x = m, \\ 0 & \text{otherwise.} \end{cases} \quad \longrightarrow \quad S_f|x\rangle = (-1)^{f(x)}|x\rangle$$

Amplify marked states using the diffusion operation:

$$D = \mathcal{A}^\dagger S_0 \mathcal{A}$$

Therefore, can iteratively apply the **Grover Iterator**:

$$Q = \mathcal{A}^\dagger S_0 \mathcal{A} S_f$$

Quantum Amplitude Amplification

The optimal number of iterations of the QAA routine \mathcal{Q} is given by

$$t = \left\lceil \frac{\pi}{4} \sqrt{\frac{N}{m}} \right\rceil$$

After t iterations of \mathcal{Q} , measurement will return a marked state with high probability

QAA therefore scales as $\mathcal{O}(\sqrt{N})$, thus achieving a **polynomial speedup** over classical search algorithms, which scale as $\mathcal{O}(N)$

Oracle Construction

Consider a two qubit example where $|11\rangle$ is the marked state

$$S_f : I \otimes |0\rangle\langle 0| + Z \otimes |1\rangle\langle 1|$$

Quantum Template Matching

The perform template matching, we must **abstract** the QAA routine by constructing a new **oracle**

Introducing a new **data register** and acting the oracle across **two registers** allows for **data** to be **parsed directly** to the algorithm

The oracle is constructed from a series of **CNOT** gates and a phase inversion about the zero state on the **template register**

The **diffusion operation** then has the same form as the regular QAA routine

$$Q = A^\dagger S_0 A S'_f$$

Quantum Template Matching for Track Finding

Quantum Track Finding with Missing Hits

A primary challenge for track finding algorithms is when a particle traverses a detector without registering a hit in one or more detector module

An Associative Memory approach to track finding cannot manage **missing hit data**

Modifying the oracle allows for the quantum template algorithm to efficiently search on missing hit data, **without an increase in resources** and retaining the **high accuracy** and **speedup**

Quantum Track Finding with Missing Hits

IBM Q

Summary

High Energy Physics is on the edge of a **computational frontier**, the High Luminosity Large Hadron Collider and FCC will provide **unprecedented amounts of data**

Quantum Computing offers an impressive and powerful tool to **combat computational bottlenecks**, both for theoretical and experimental purposes

The **first realistic simulation** of a **high energy collision** has been presented using a compact **quantum walk** implementation, allowing for the algorithm to be run on a **NISQ device**

We present an **efficient** approach to track finding using quantum computers by exploiting the **QAA** routine and employing a **novel oracle** paving the way for **practical quantum track finding**

Noisy Intermediate-Scale Quantum Devices

NISQ devices:

No continuous quantum error correction, prone to large noise effects from environment.

Quantum errors:

Multiqubit qubit gates: CNOT gates have higher associated errors than single qubit gates.

SWAP errors: SWAP operations require 3 CNOT gates

T1 times: The time it takes for an excited qubit to decay back to the ground state.

Circuit depth! - Compact circuits needed!

Transpilation:

Loading the circuit onto the backend, transpilation can be used to optimise the circuit: **qubit and coupling mapping, noise models, etc.**

Speed up via Quantum Walks

Quantum Walks have long be conjectured to achieved at least **quadratic speed up**

Szegedy Quantum Walks have been proven to achieve quadratic speed up for **Markov Chain Monte Carlo**

This has been proven under the condition that the MCMC algorithm is **reversible and ergodic**

Work is ongoing to prove this is true for all QWs, but latest upper limits are on par with classical RW

Quantum Walks with Memory

Qubit model:

Augment system further by adding an additional memory space

$$\mathcal{H} = \mathcal{H}_P \otimes \mathcal{H}_C \otimes \mathcal{H}_M$$

Advantages:

- Arbitrary dynamics
- Classical dynamics in unitary evolution

Disadvantages:

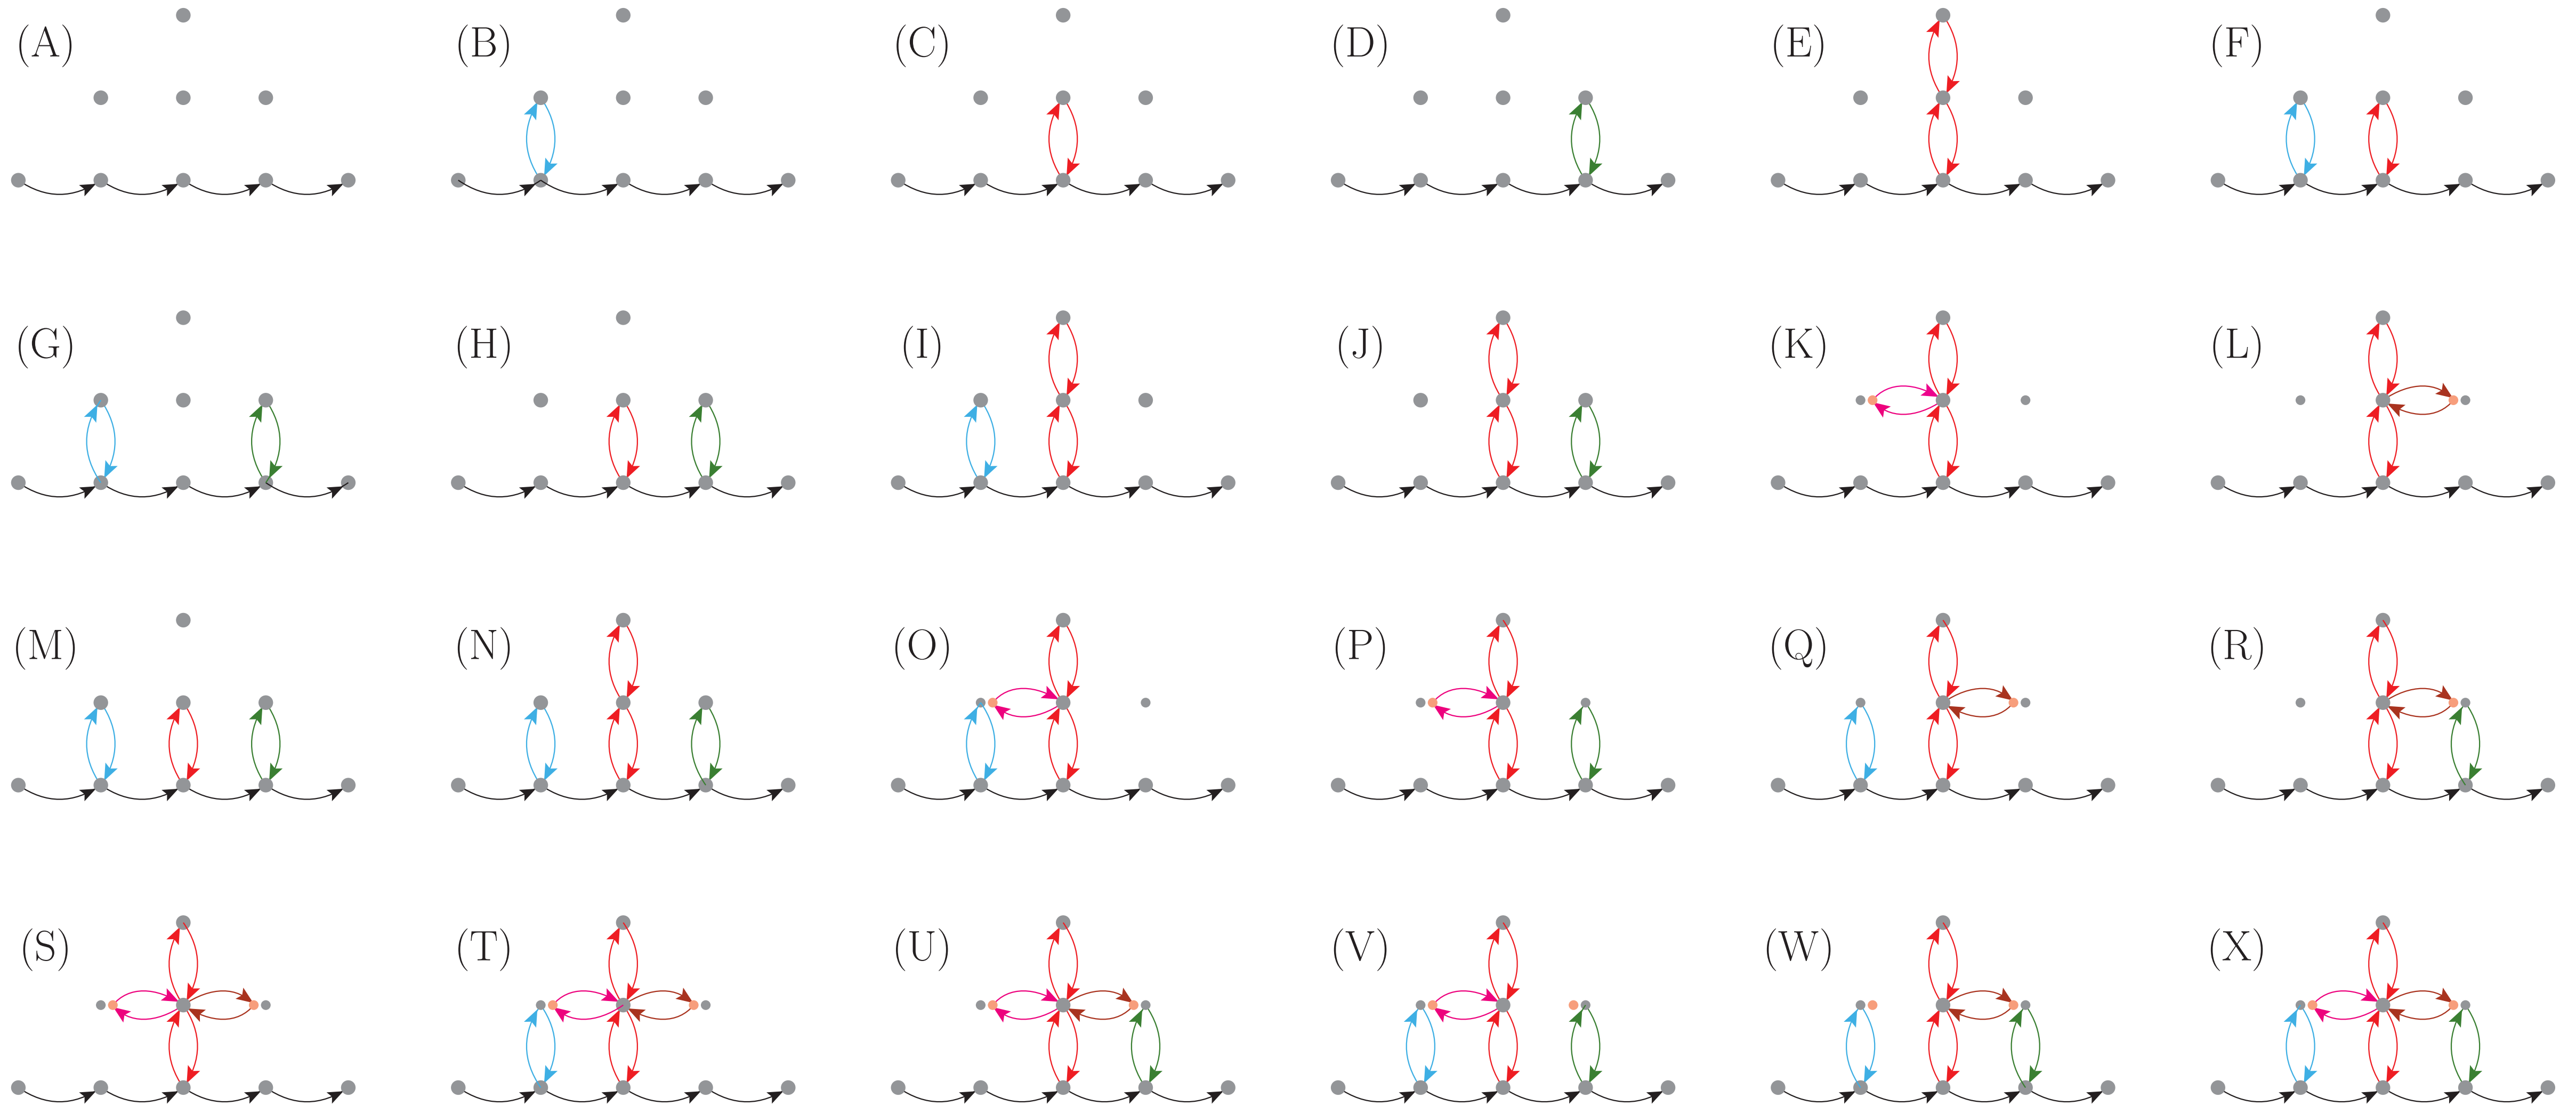

- Tight conditions on quantum advantage

Quantum Parton Showers:

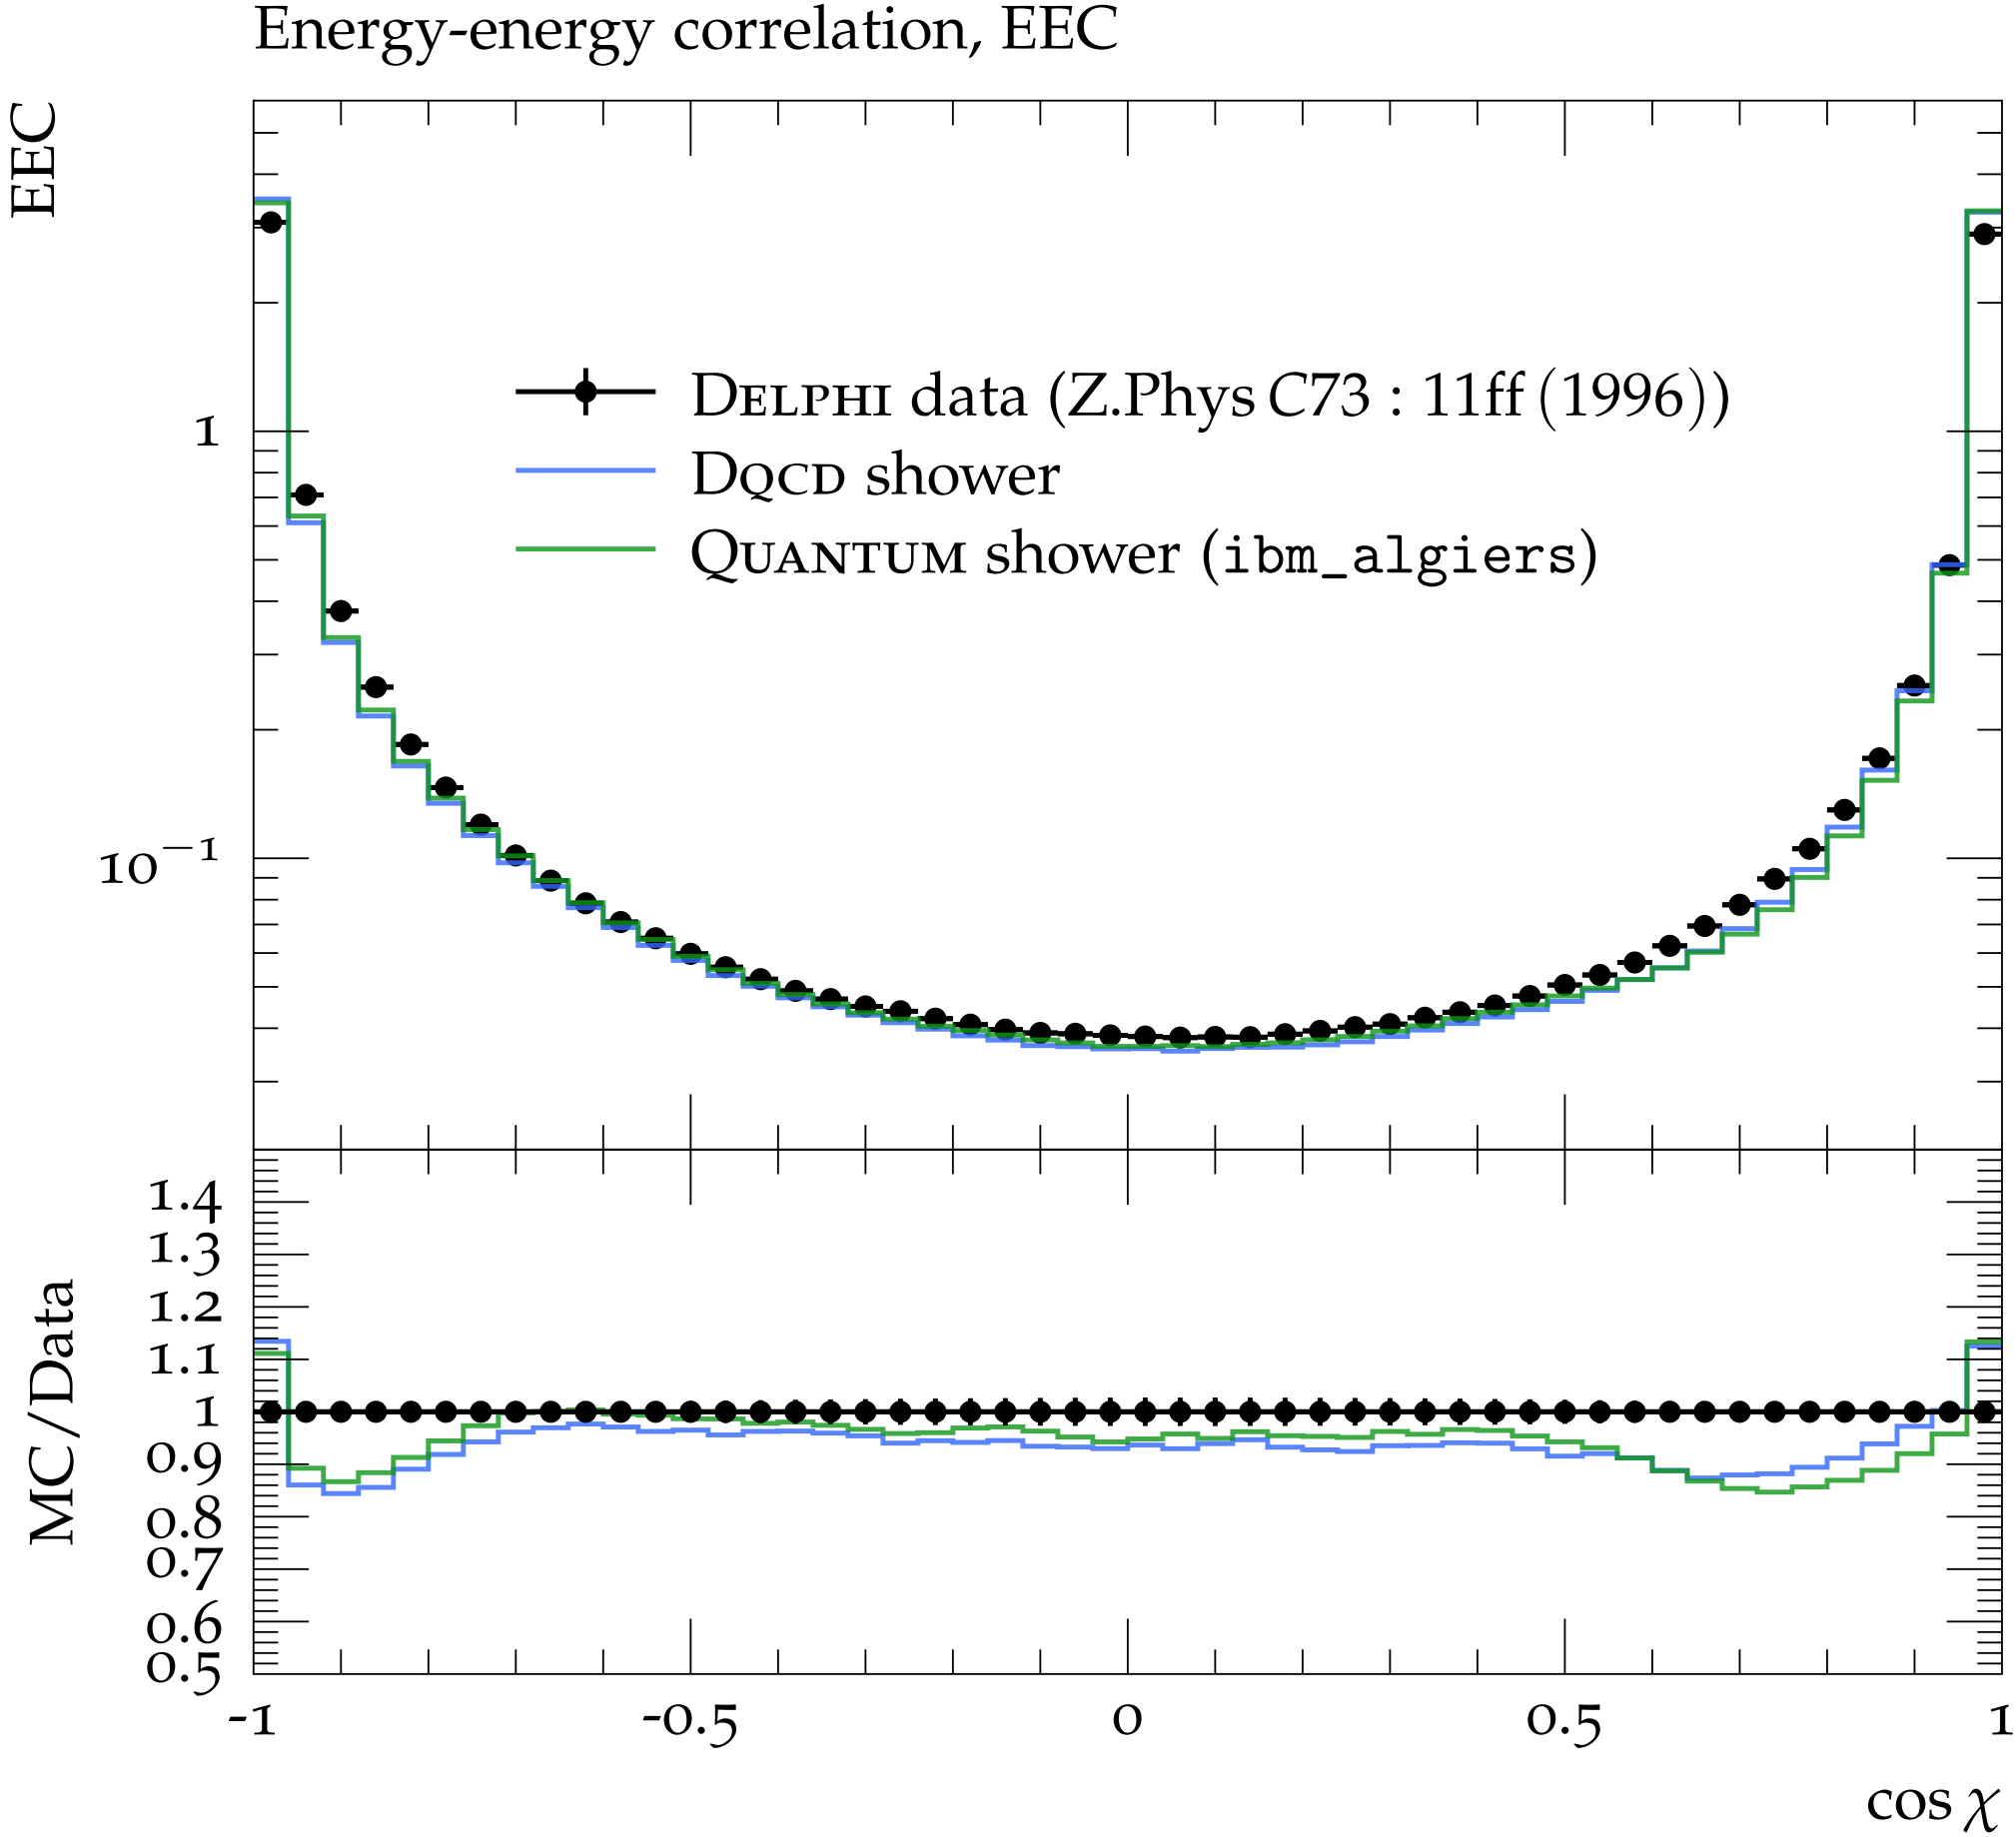

Quantum Walks with memory have proven to be very useful for quantum parton showers.

K. Bepari, S. Malik, M. Spannowsky and SW, Phys. Rev. D 106 (2022) 5, 056002

Discrete QCD - Grove Structures

Collider Events on a Quantum Computer

Collider Events on a Quantum Computer - Varying Λ

Varying values for the mass scale Λ . This leads to non-negligible uncertainties, however this is expected from a leading logarithm model.

Collider Events on a Quantum Computer - Varying Λ

Varying values for the mass scale Λ . This leads to non-negligible uncertainties, however this is expected from a leading logarithm model.

Collider Events on a Quantum Computer

Collider Events on a Quantum Computer - Changing tune

Observables dominated by non-perturbative dynamics show mild dependence on the mass scale Λ , but are highly sensitive to changes in the tune.
