Introduction

The problem of measuring the Cosmic Rays flux

Primary Cosmic Rays generate *Extensive Air Showers* typically 20-50 km of altitude

Primary Cosmic Rays are
mostly protons and light
nuclei...

so they are affected by –
galactic, solar, terrestrial –
magnetic fields

**Coronal
Mass
Ejections
(CME)**

**Forbush
Decrease
(FD)**

Our proposal

The miniTRASGO Cosmic Ray Telescope

The TRASGO project

Muons, electrons...

- Measure **secondary charged cosmic rays** with *tracking*
 - *Not only counts, but angular counts!*
- TRASGO concept: **TRAck reconStructinG bOx**

RPC based!

TRISTAN

STRATOS

TRAGALDABAS

The HUGE TRASGO ???

The miniTRASGO !

The miniTRASGO !

Main features:

- Versatile and **compact**
- Not cost demanding
 - **<12000 euro!**
- **Standardizable**
- **Stable**

The miniTRASGO !

Main features:

- Versatile and **compact**
- Not cost demanding
 - **<12000 euro!**
- **Standardizable**

Ideal for a network!

But...

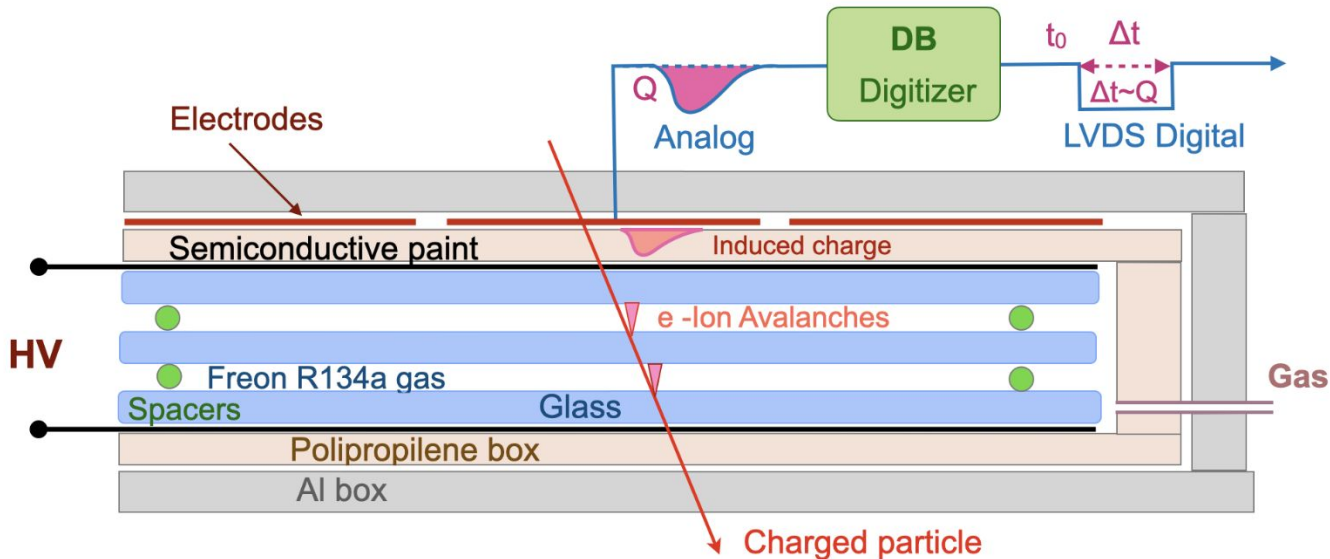

***... are they good
counting detectors?***

RPCs in miniTRASGO

Understanding the device

RPC summary

- **4 parallel square Multigap glass RPC**
 - 3 glass layers, 2 mm each
 - 2 gaps, 1 mm each (nylon monofilaments)
- **High Voltage:** WP ~ 5.52 kV/gap (painted glass)
- **Resistivity:** $10 \text{ M}\Omega/\text{cm}^2 = 10^7 \Omega/\text{cm}^2$
- **Gas:** R134a, flux of 1 kg/month
- **Active area:** 30x30 cm, approx. 0.1 m^2

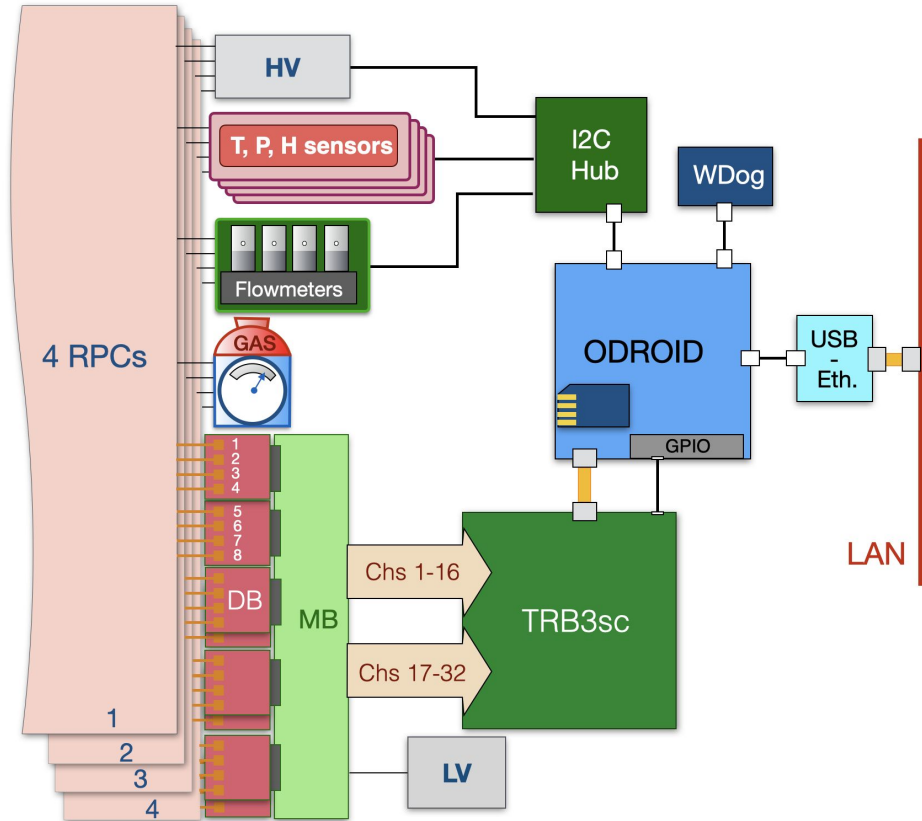

Compact and autonomous

Only three connections:

- **Power** (standard plug)
- **Gas** bottle (15 kg)
- **Ethernet** (not required)

Includes:

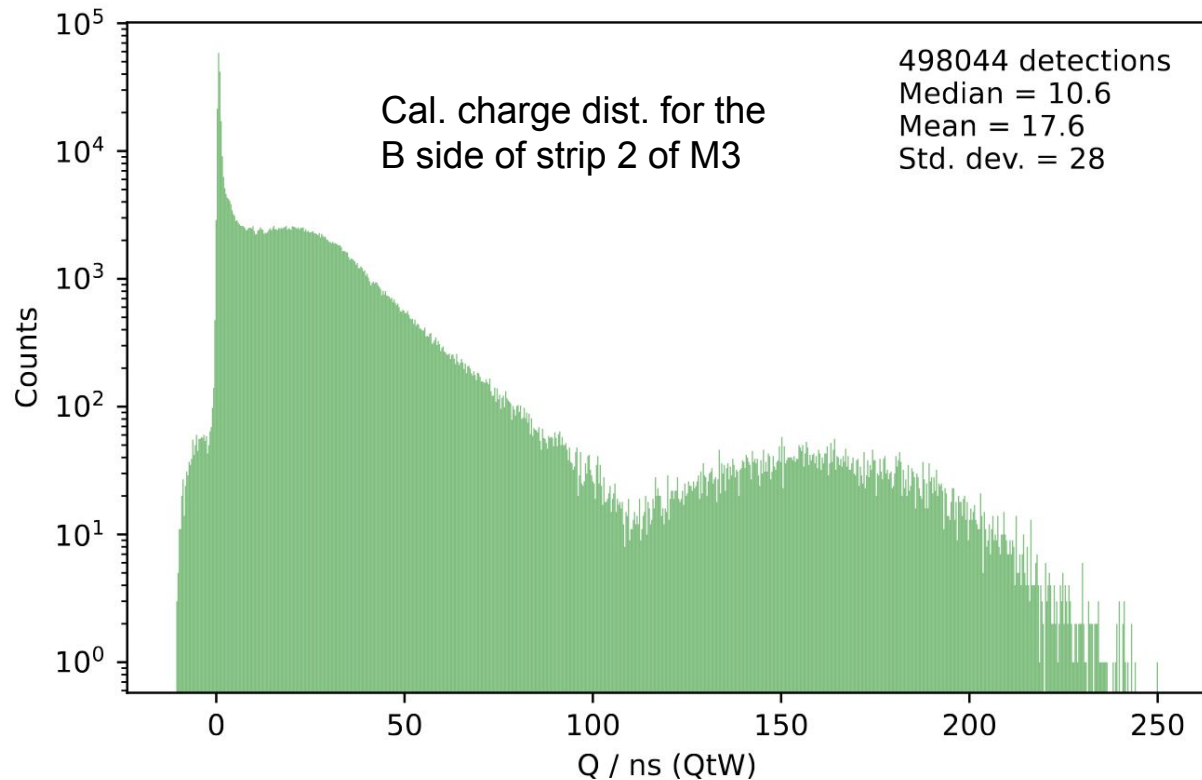

- environment sensors, flowmeters, DAQ and a PC for data analysis and storage

Measure: time and charge in F and B per strip

Time sum → Incidence time
Time diff → Position
Charge sum → Total charge
Charge diff → Monitor

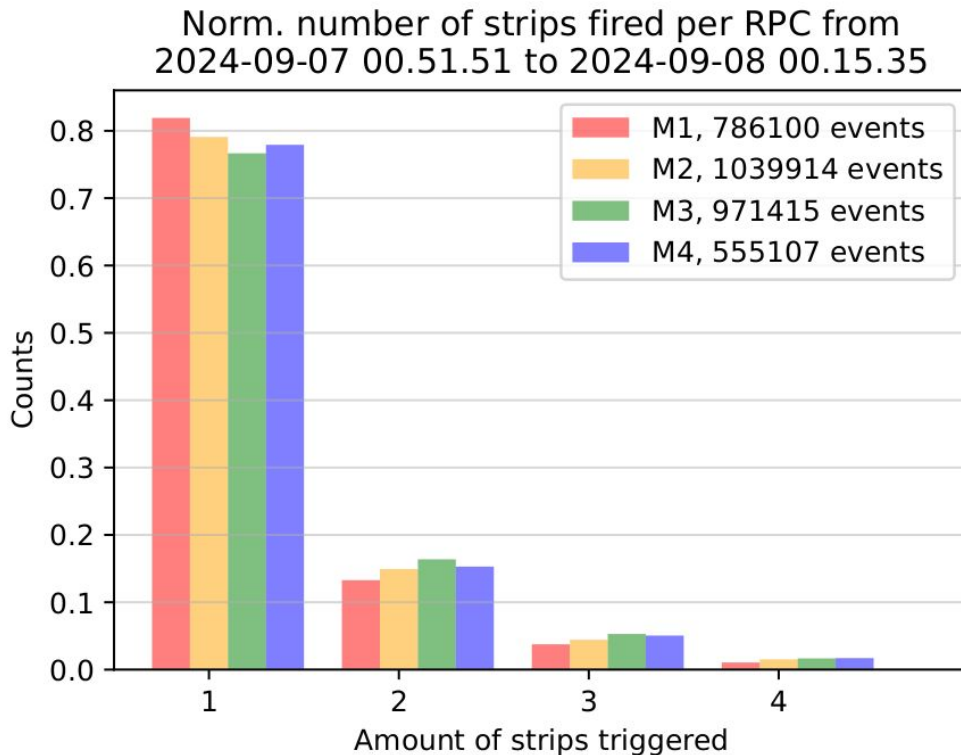

Cluster size

- ~80% of events leave charge in only one strip
- ~10-20 % of events in two strips
- ~5% in three

*But first, charge spectra
must be understood*

Madrid - Minimum charge per strip in triple hits
from 2024-09-08 00.15.35 to 2024-09-08 23.59.23

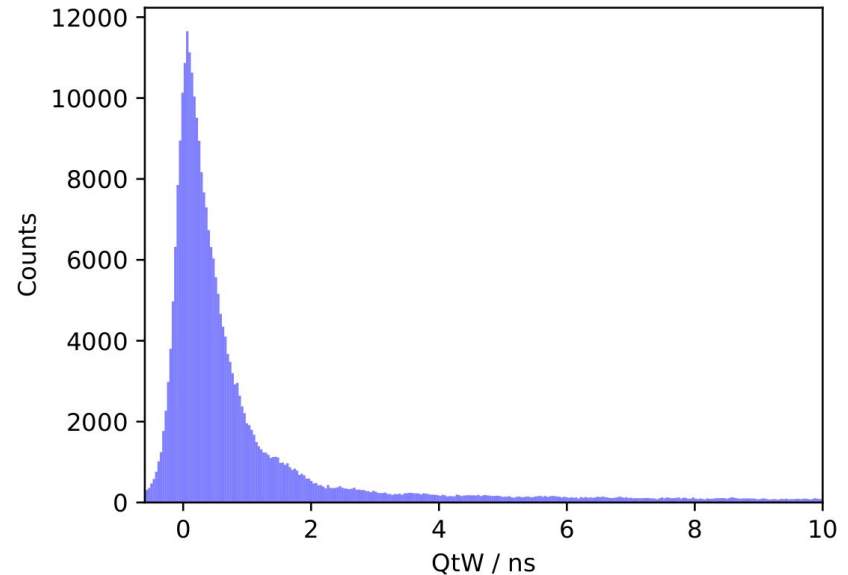

We learn:

- 1 ns of QtW charge is a reasonable upper bound for the crosstalk charge.
- **Cluster Size = 3 cases are mainly caused by crosstalk, so in practice can be considered Cluster Size = 2**

Crosstalk and Cluster Size 3 study

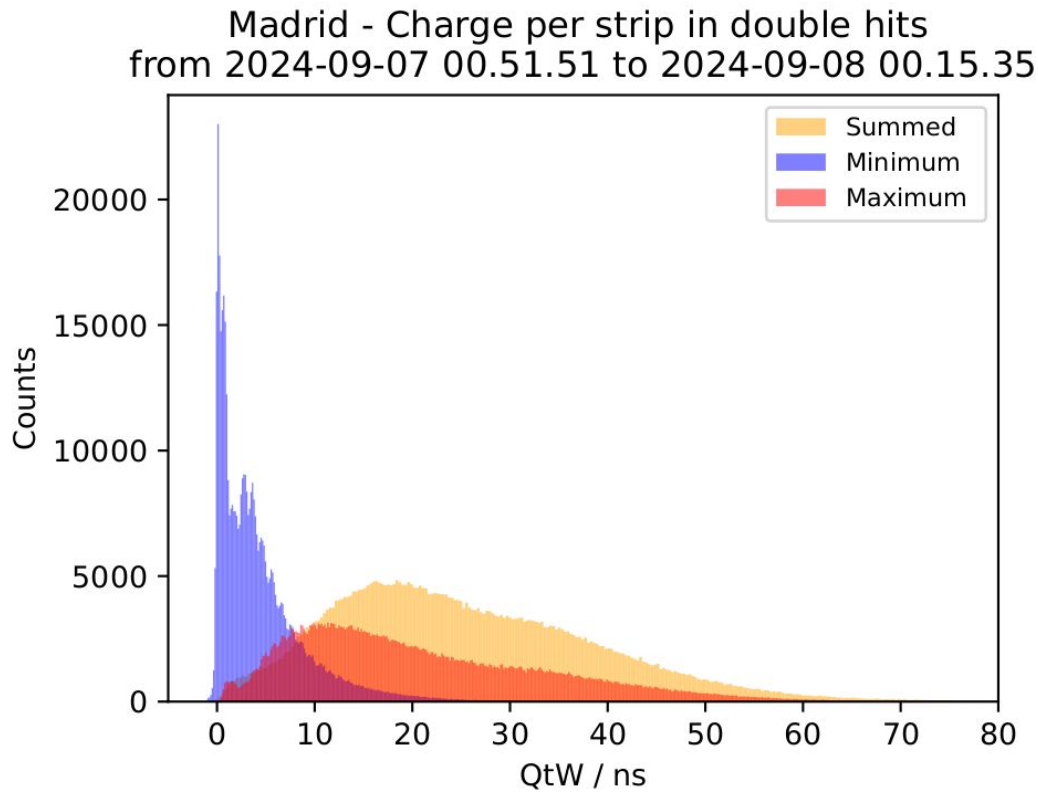

Madrid - Two minimum charges per strip in triple hits
from 2024-09-07 00.51.51 to 2024-09-08 00.15.35

What about Cluster Size 2?

The same plot reveals a wider distribution:

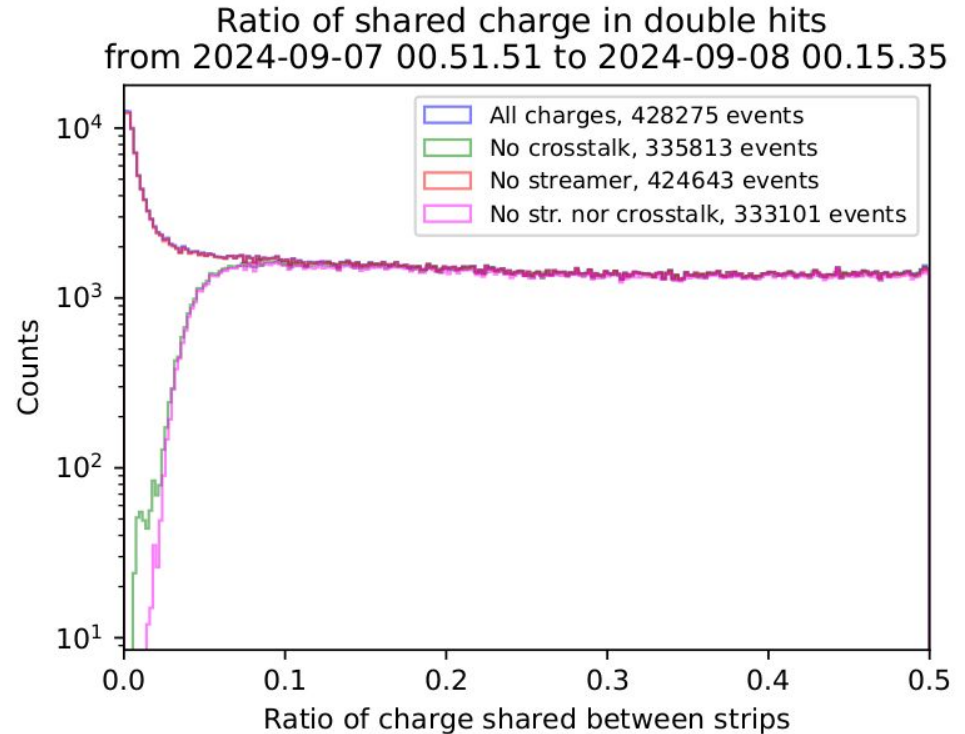

- **There is charge sharing in between two strips, but not three.**
- Induction section can be estimated

And sharing goes uniformly from 10% to the 50% of charge

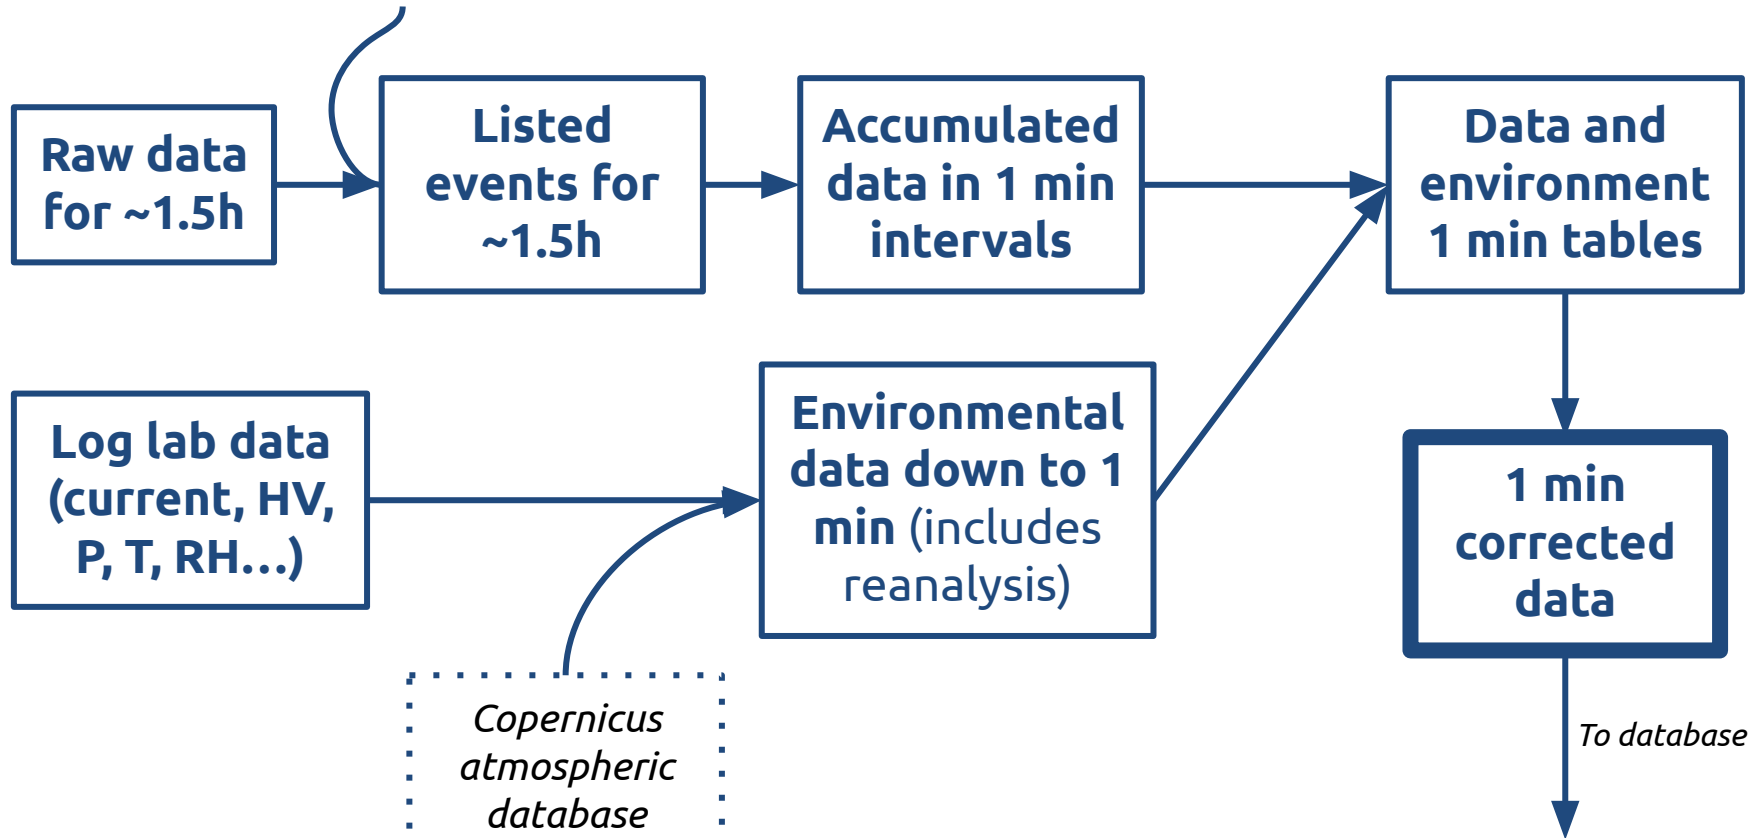

If the mean strip width is **63 mm**:

- Induction section = 2×9.8 mm = 20 mm = **~2 cm**
- Consistent with the resistivity of these RPCs: **$10^7 \Omega/\text{cm}^2$**

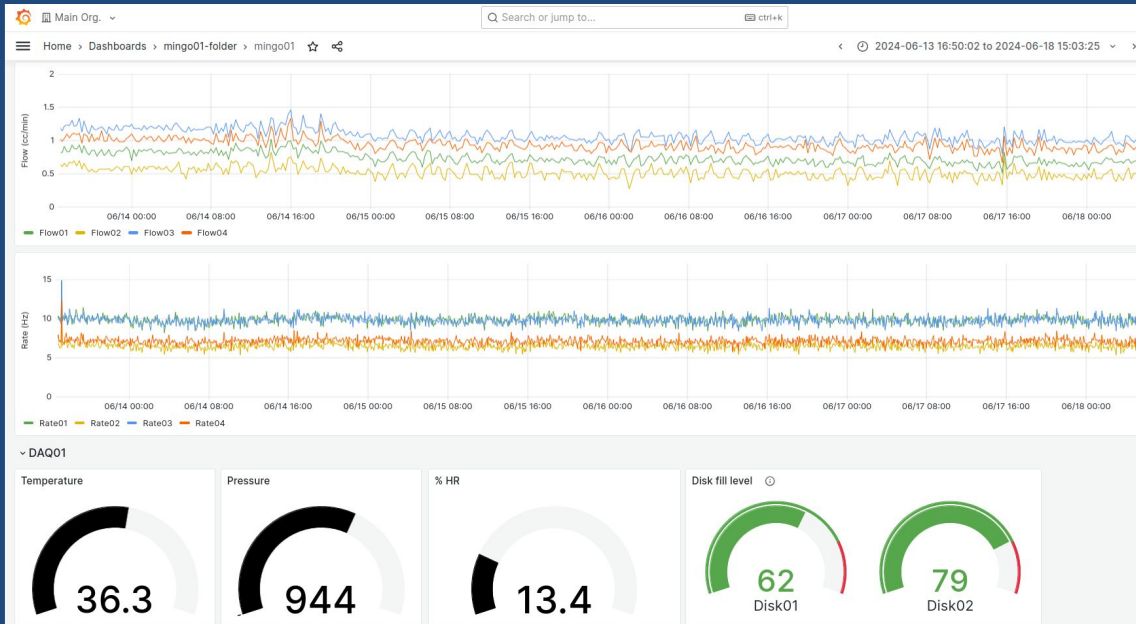

Efficient dataflow for Cosmic Ray Data

TimTrack algorithm

Grafana and Telegram control

minGO_Madrid bot

- /create_report: creates the pdf report.
- /send_original_report: send the pdf report generated in the mingo itself.
- /send_monitoring_report: send the pdf report with the information per channel.
- /send_daq_report: send the pdf report of charges and multiplicities processed over one day.
- /send_results_vs_time_report: send the pdf report of evolution of some quantities as well as logs.
- /send_weekly_results_report: same, but for the previous week.

Emergency and assistance:

- /restart_tunnel: closes the tunnel so it reopens automatically.

/send_external_environment 15:01 ✓

Conclusions

and a look into the future

Future prospects

- **Stable, not expensive, standardizable** secondary charged cosmic ray detector **presented**
- *Forbush Decrease* detection
 - **good counting detector**
- **Tracking** allows
 - **robust rates** and **original angular studies**
- **Working as a network (next talk)**
 - open the realm of **muon Earth coverage**

Thank you! *Questions?*

The miniTRASGO Cosmic Ray Telescope

XVII Conference on RPCs and Related Detectors

Back-up slides

for those curious

Analysis of Event Distribution

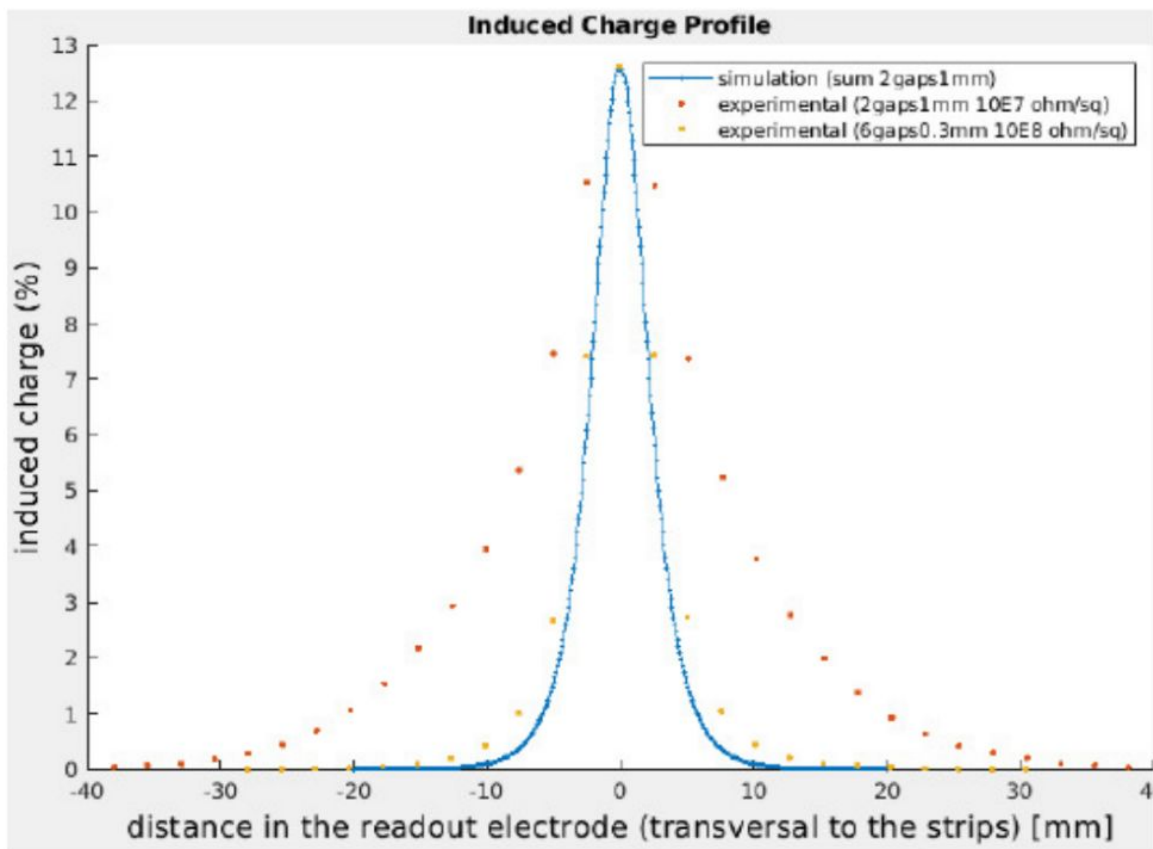

- **80%** of total events are in only one strip.
- **20% in two strips, we check numbers in histogram of charge ratio min/max:**
 - **78%** are double adjacent sharing charge → **15%** of total events.
 - **23%** are actually single hits → **5%** of total events.

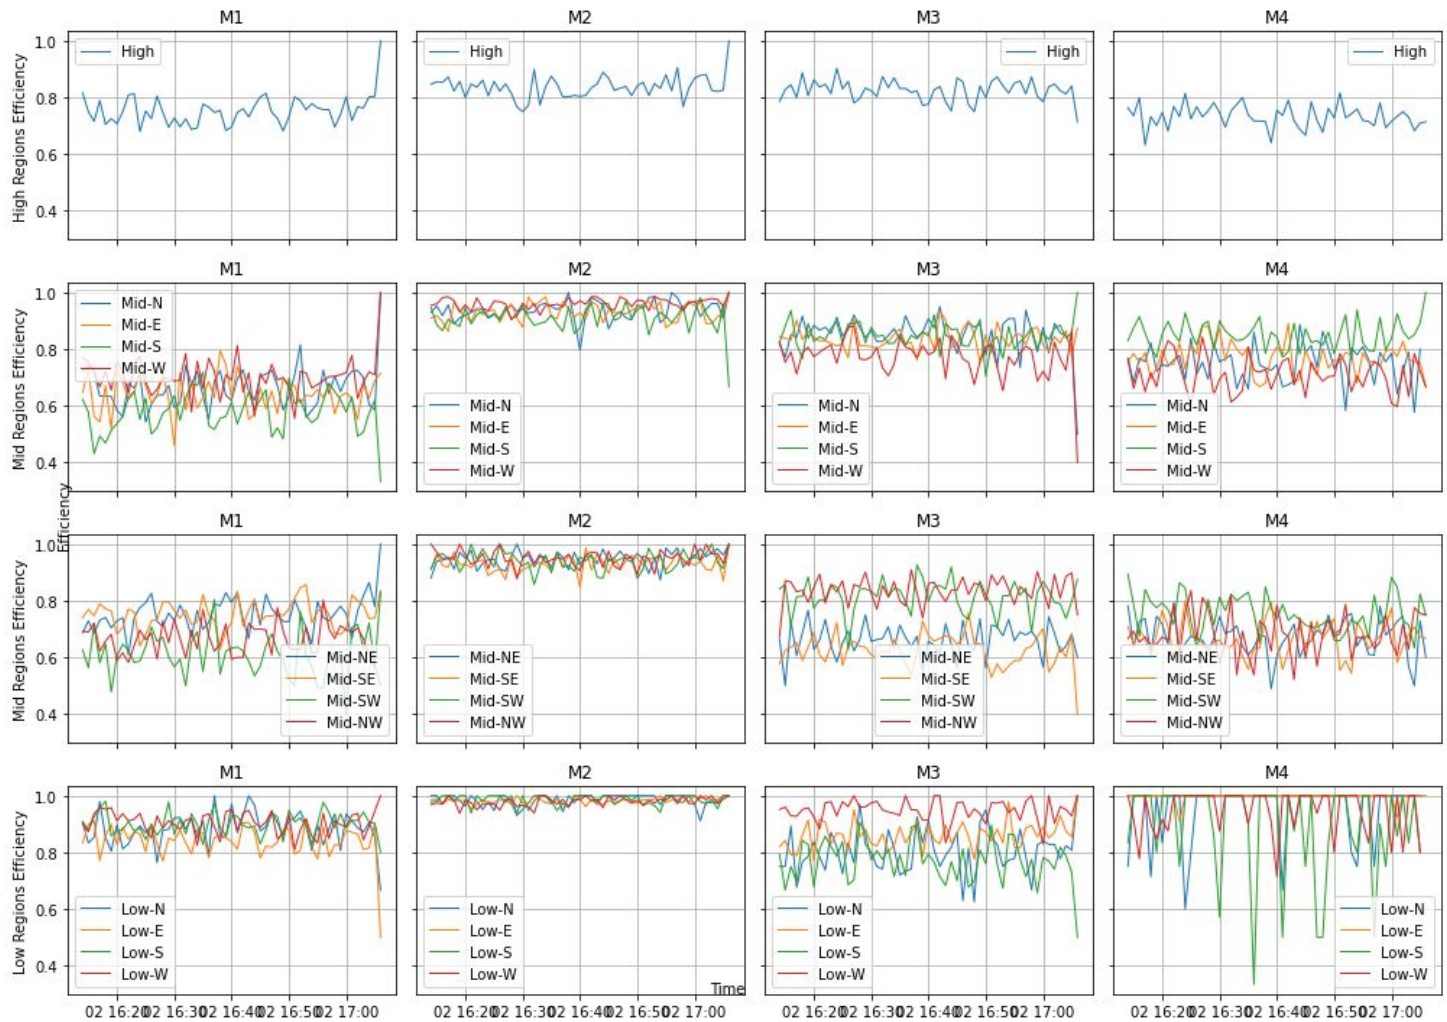

Classification Breakdown

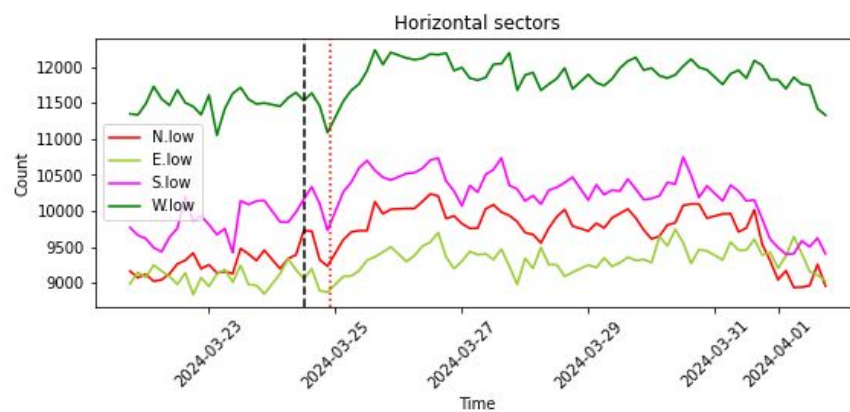

- **85%** of total events = one particle in the interior of one strip (80% + 5%).
- **15%** of total events = one particle between two strips.

Ionization Section

- If the mean strip width = **63 mm**:
 - Ionization section = **$2 \times 9.8 \text{ mm} = 20 \text{ mm}$** (2 cm).
 - Consistent with the resistivity of these RPCs

DAQ Overview

- **Front-end electronics (FEE):** Developed for the **HADES detector** (GSI).
 - Daughterboards (DB): Converts RPC signals into LVDS (Low Voltage Differential Signal) using Hidronav technology. Key features:
 - Motherboard (MB): Powers DBs and transfers LVDS to the TRB.
- **TRB3sc** (Time-of-Flight Reconstruction Board): From HADES experiment.
 - **32** Time-to-Digital Converters (TDC).
 - Inputs LVDS from DB.
 - Outputs **digital timestamp** and **signal length** via USB.
