

RECENT DEVELOPMENTS IN FORMAL THEORY

Towards all-loop scattering amplitudes

Jaroslav Trnka

Center for Quantum Mathematics and Physics (QMAP),
University of California, Davis, USA

PROGRESS IN AMPLITUDES

Wide field which spreads between formal theory, collider physics and newly also gravitational physics

precision physics,
calculation of higher-loop
Feynman integrals
relevant for colliders

exploring new theoretical
methods in “toy models”:
with potential
general applications

applications to gravitational
wave physics and cosmology

PROGRESS IN AMPLITUDES

Wide field which spreads between formal theory, collider physics and newly also gravitational physics

precision physics,
calculation of higher-loop
Feynman integrals
relevant for colliders

**exploring new theoretical
methods in “toy models”:
with potential
general applications**

applications to gravitational
wave physics and cosmology

SCATTERING PROCESS

Scattering of elementary particles: predictions of outcomes

many possible outcomes
we can only talk about probabilities

$$\sigma = \int d\Omega |A|^2$$

cross section amplitude

Calculating amplitudes: at weak coupling in principle solved

PERTURBATION THEORY

Perturbation theory: series expansion in g

$$A_n \sim A_n^{\text{tree}} + g^2 A_n^{1\text{-loop}} + g^4 A_n^{2\text{-loop}} + g^6 A_n^{3\text{-loop}} + \dots$$

asymptotic series

Feynman diagrams: diagrammatic organization

Main object of interest: amplitudes in QCD

needed for Standard model background

most complex part: **gluon amplitudes**

standard procedure:
Feynman diagrams

PRE-HISTORY

Calculation of gluon amplitudes: status in late 1970s

Most complicated process:
2->3 process = 5pt amplitude
at tree-level

Brute force calculation:
24 pages of result

$$(k_1 \cdot k_4)(\epsilon_2 \cdot k_1)(\epsilon_1 \cdot \epsilon_3)(\epsilon_4 \cdot \epsilon_5)$$

SSC approved in 1983: higher-point calculations needed

Energy 40 TeV: many gluons!
Next on the list: 6pt amplitude
 $gg \rightarrow gggg$

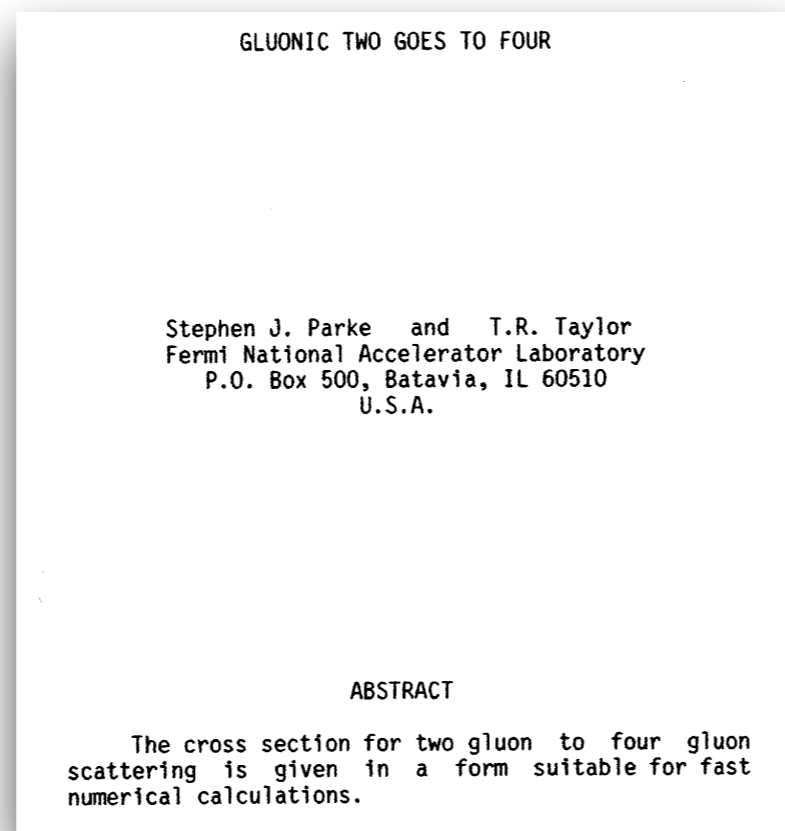

PARKE-TAYLOR FORMULA

Calculation completed in 1984

220 Feynman diagrams, 100 pages of algebra

(Parke, Taylor)

result compressed
to 14-page paper

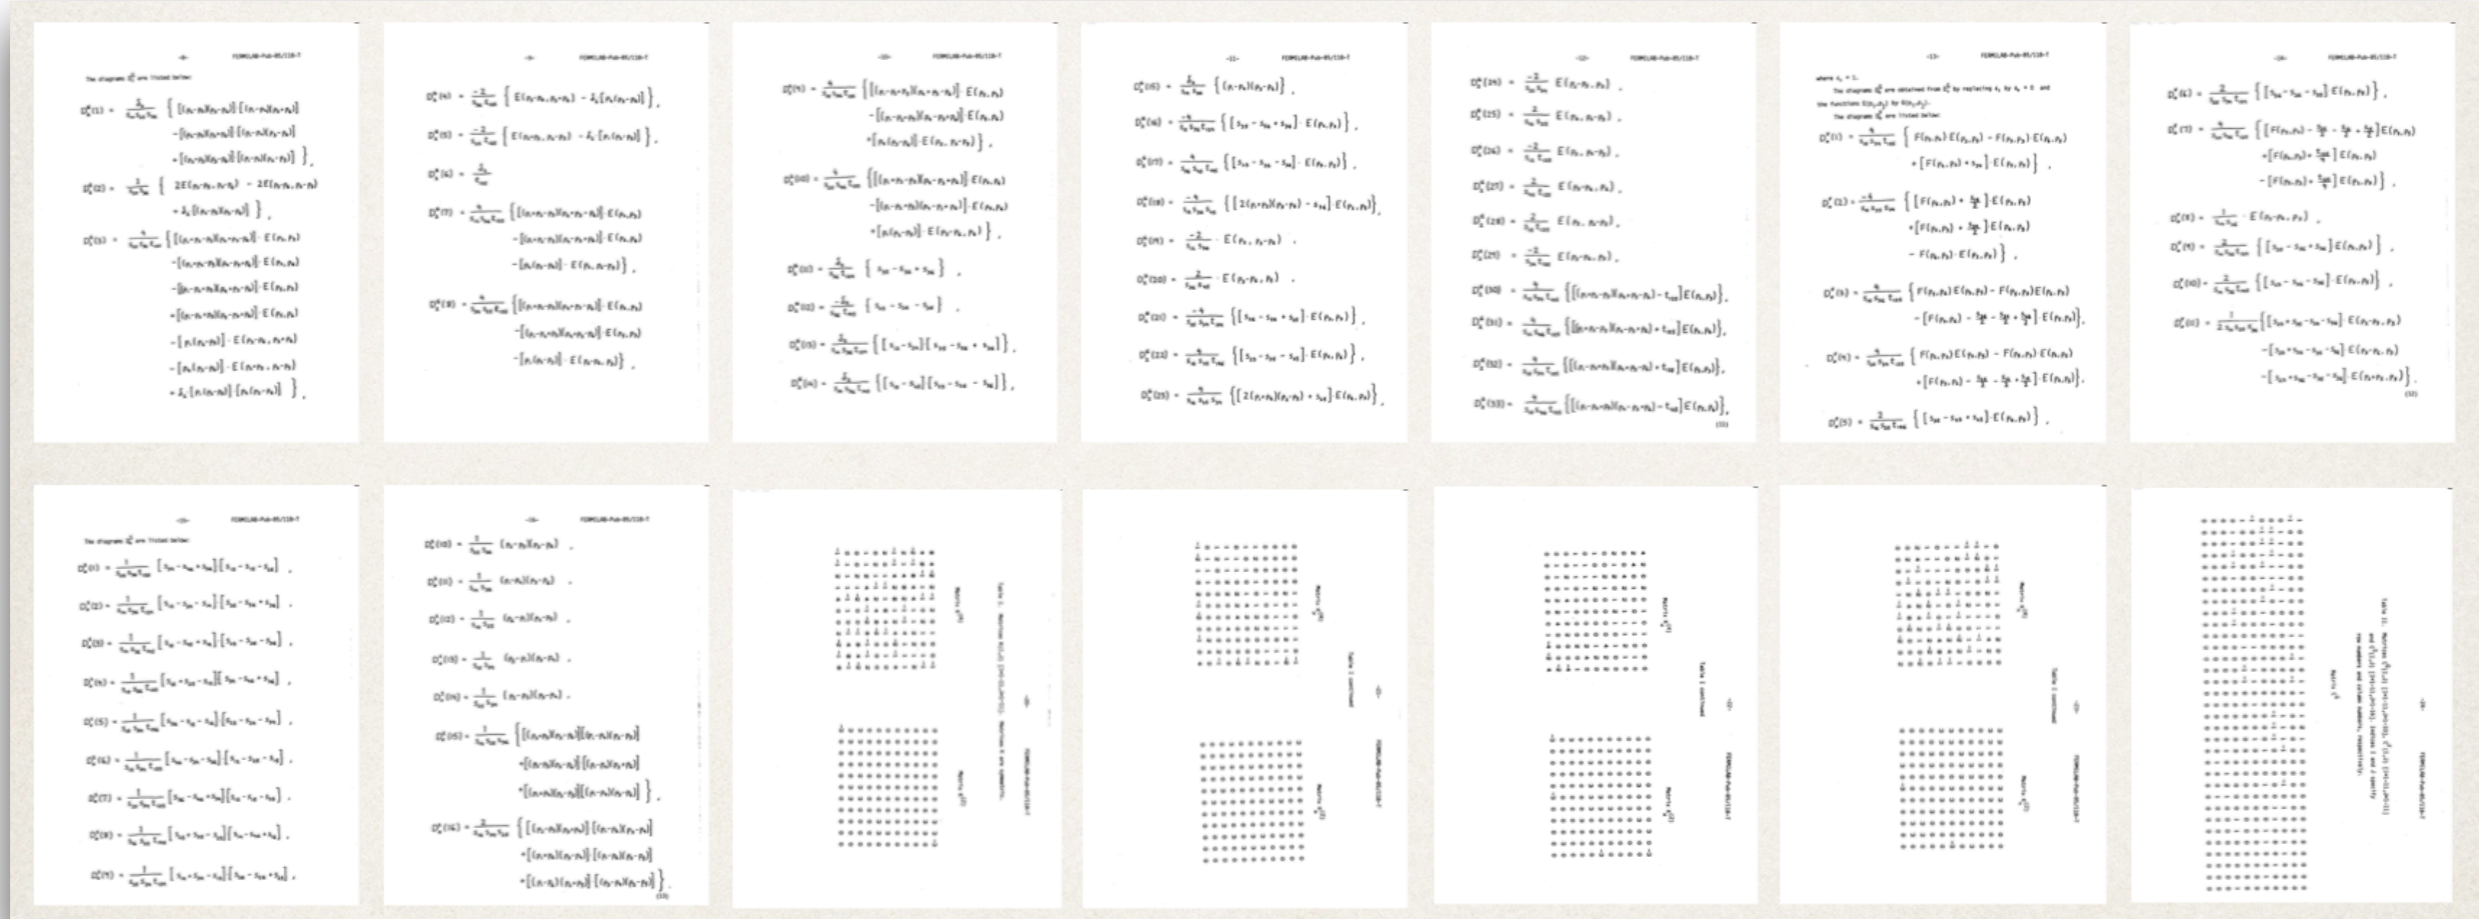

PARKE-TAYLOR FORMULA

Calculation completed in 1984

220 Feynman diagrams, 100 pages of algebra

(Parke, Taylor)

PARKE-TAYLOR FORMULA

Calculation completed in 1984

220 Feynman diagrams, 100 pages of algebra

(Parke, Taylor)

Conclusion of the paper:

Our result has successfully passed both these numerical checks.

Details of the calculation, together with a full exposition of our techniques, will be given in a forthcoming article. Furthermore, we hope to obtain a simple analytic form for the answer, making our result not only an experimentalist's, but also a theorist's delight.

PARKE-TAYLOR FORMULA

Calculation completed in 1984

220 Feynman diagrams, 100 pages of algebra

(Parke, Taylor)

Conclusion of the paper:

Our result has successfully passed both these numerical checks.

Details of the calculation, together with a full exposition of our techniques, will be given in a forthcoming article. Furthermore, we hope to obtain a simple analytic form for the answer, making our result not only an experimentalist's, but also a theorist's delight.

Within a year of the publication they found an extraordinary simplification:

$$|A_6|^2 \sim \frac{(p_1 \cdot p_2)^3}{(p_2 \cdot p_3)(p_3 \cdot p_4)(p_4 \cdot p_5)(p_5 \cdot p_6)(p_6 \cdot p_1)}$$

MODERN METHODS

What is the scattering amplitude?

Feynman diagrams

Analytic S-matrix:
not successful

Modern methods use both:

- Expose simplicity of amplitudes
- Use perturbation theory

Many new methods: generalized unitarity,
recursion relations, string-based methods,...

(Bern, Dixon, Kosower)

TREE-LEVEL AMPLITUDES

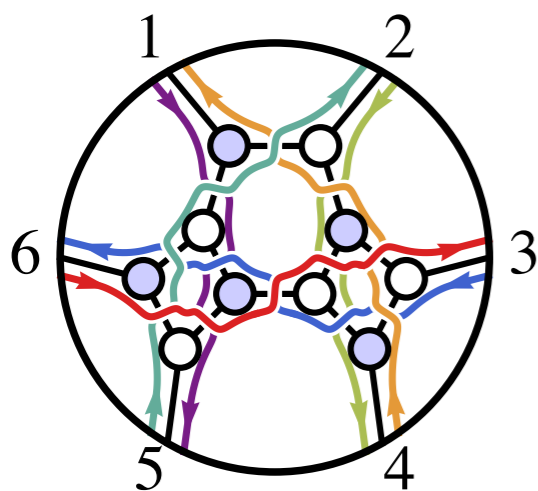

Very efficient recursion relations

	$gg \rightarrow 4g$	$gg \rightarrow 5g$	$gg \rightarrow 6g$
Feynman diagrams	220	2485	34300
Terms in recursion	3	6	20

(Britto, Cachazo, Feng, Witten 2005)

For gluon amplitudes:
very efficient implementation

on-shell diagrams
positive Grassmannian

(Arkani-Hamed, Bourjaily, Cachazo,
Goncharov, Postnikov, JT)

7pt amplitude

my colleague

7pt amplitude

Hello,
Here is the amplitude:
(3,1,6,4,5,2,7)
(2,1,5,7,3,6,4)
(4,3,7,5,6,1,2)
(6,1,3,2,5,7,2)
(1,6,2,7,3,4,5)
(5,3,2,7,6,4,1)
Enjoy!

2485 Feynman diagrams

LOOP AMPLITUDES

Loop amplitude: complicated function of kinematics

$$A_n^{\ell\text{-loop}} = \int d^{4\ell}L \mathcal{I}_n^{\ell\text{-loop}}$$

transcendental functions

$\log, \text{Li}_2, G_{a_1, a_2, \dots, a_m}, \dots$

loop
integration

rational function:
“loop integrand”

Unitarity methods: re-organizational of the expansion

$$\mathcal{I}_n^{\ell\text{-loop}} = \sum_k c_k B_k$$

calculate coefficients
from cuts

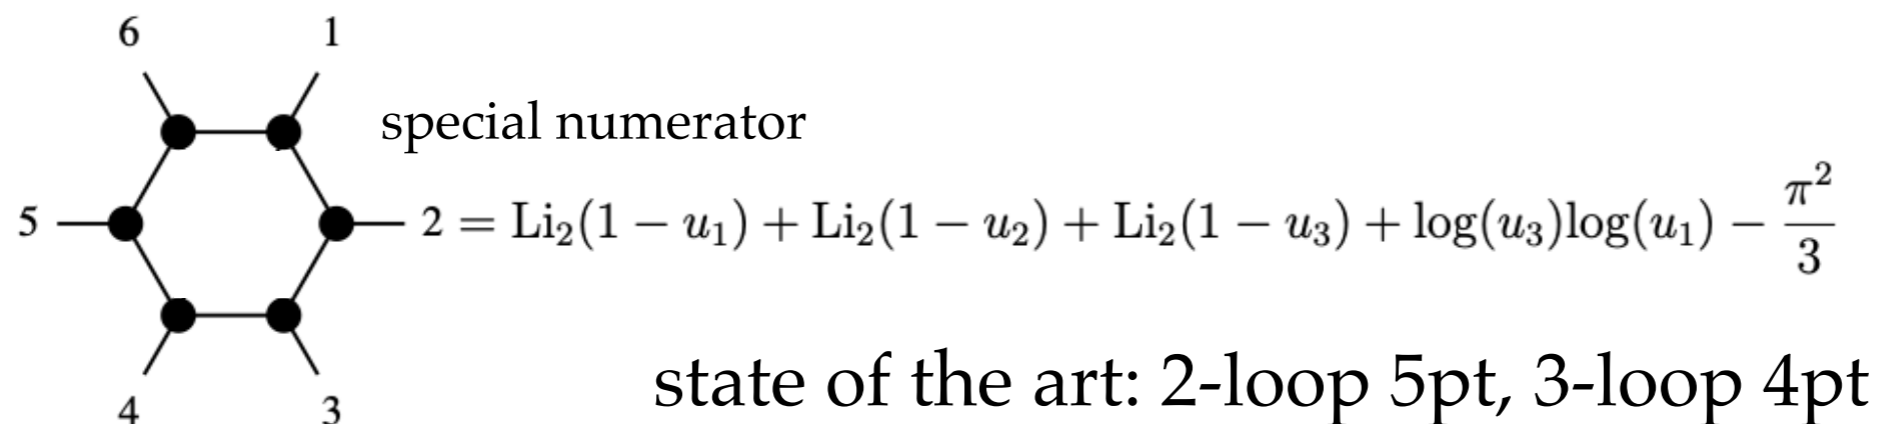

basis integrals to
calculate: critical
to choose good basis

IBP methods, differential equations,...

LOOP INTEGRATION

Lesson learnt: convenient choice of integrals dramatically simplifies calculation, sometimes you get result almost for free

make analytic properties, UV and IR manifest

special numerator

$$2 = \text{Li}_2(1 - u_1) + \text{Li}_2(1 - u_2) + \text{Li}_2(1 - u_3) + \log(u_3)\log(u_1) - \frac{\pi^2}{3}$$

state of the art: 2-loop 5pt, 3-loop 4pt

Mathematical properties: transcendentality, bootstrap methods, cluster algebras, differential equations

Time-proven method: develop the methods in toy models, provides a useful organizational principle

SIMPLEST QFT

Planar N=4 super Yang-Mills theory: our favorite toy model

- ❖ maximal supersymmetry in $D=4$, superpartners to gluons, cancelations
- ❖ limit of an infinite number of colors, only planar diagrams contribute
- ❖ AdS/CFT correspondence: dual to supergravity

What do we lose?

- ❖ UV finite theory, no confinement

Why is it a good toy model?

- ❖ tree-level amplitudes of gluons: same as in QCD
- ❖ loop amplitudes simpler, convergent perturbative series
- ❖ past experience: new computational methods developed first here

HIGHER LOOP CALCULATIONS

Huge simplifications in planar N=4 SYM amplitudes

in some cases due to symmetries of the theory, otherwise unexplained

Integrands of 2->2 scattering amplitudes calculated up to 11-loops

(Bern, Dixon, Kosower 2005,.... Bourjaily, Heslop, Tran 2016)

number of Feynman diagrams
grows very very fast, but even in
the most compressed form the
result is complicated

progress on integration using
new techniques (dlog forms,
differential equations)

ℓ	number of planar DCI integrands
1	1
2	1
3	2
4	8
5	34
6	284
7	3,239
8	52,033
9	1,025,970
10	24,081,425
11	651,278,237

SYMBOLS

Skip the integrand step, using the knowledge of the function space to construct the amplitude directly

Reduce information in the function to a **symbol**

(Goncharov, Spradlin, Vergu, Volovich 2009)

$$\mathcal{S}(f^{(k)}) = \sum_{\vec{\alpha}} \underbrace{\phi_{\alpha_1} \otimes \dots \otimes \phi_{\alpha_k}}_{\left\{u, v, w, 1-u, 1-v, 1-w, y_u, y_v, y_w\right\}} \quad \leftarrow \text{encodes branch cuts}$$

$\left\{u, v, w, 1-u, 1-v, 1-w, y_u, y_v, y_w\right\} \quad \leftarrow \text{symbol letters}$

This originated from another surprising simplification

In 2009 Del Duca, Duhr and Smirnov calculated a certain 2-loop 6pt amplitude in the planar N=4 SYM theory, 30 pages of result

SYMBOLS

$$\begin{aligned}
 & G\left(0, \frac{1}{1-\frac{u_1}{u_3}}, 1; 1\right) \ln u_1 + G\left(\frac{1}{1-u_2}, 0, 1; 1\right) \ln u_1 + G\left(\frac{1}{1-u_2}, 1, 1; 1\right) \ln u_1 + G\left(\frac{1}{1-u_2}, 1, \frac{1}{1-u_2}; 1\right) \ln u_1 \\
 & G\left(\frac{1}{1-\frac{u_1}{u_3}}, 0, 1; 1\right) \ln u_1 + G\left(\frac{1}{1-\frac{u_1}{u_3}}, 1, 0; 1\right) \ln u_1 - 2G\left(\frac{1}{1-u_2}, 1, 1; 1\right) \ln u_1 \\

 & G\left(\frac{1}{1-u_2}, 1; v\right) \ln u_1 + G\left(\frac{1}{1-u_2}, \frac{1}{1-u_2}; 1\right) \ln u_1 -
 \end{aligned}$$

SYMBOLS

The 30 pages result simplifies into a single line formula

$$R_6^{(2)}(u_1, u_2, u_3) = \sum_{i=1}^3 \left(L_4(x_i^+, x_i^-) - \frac{1}{2} \text{Li}_4(1 - 1/u_i) \right) - \frac{1}{8} \left(\sum_{i=1}^3 \text{Li}_2(1 - 1/u_i) \right)^2 + \frac{1}{24} J^4 + \frac{\pi^2}{12} J^2 + \frac{\pi^4}{72}.$$

This can be seen when writing down the symbol

$$\begin{aligned} & \mathcal{S}(R_6^{(2)}) \\ &= -\frac{1}{8} \left\{ \left[u \otimes (1-u) \otimes \frac{u}{(1-u)^2} + 2(u \otimes v + v \otimes u) \otimes \frac{w}{1-v} + 2v \otimes \frac{w}{1-v} \otimes u \right] \otimes \frac{u}{1-u} \right. \\ & \quad \left. + \left[u \otimes (1-u) \otimes y_u y_v y_w - 2u \otimes v \otimes y_w \right] \otimes y_u y_v y_w \right\} + \text{permutations}, \end{aligned}$$

Write the symbol for 30 pages, almost everything cancels, and then promote the symbol to a function

Hexagon bootstrap: write down consistent symbol

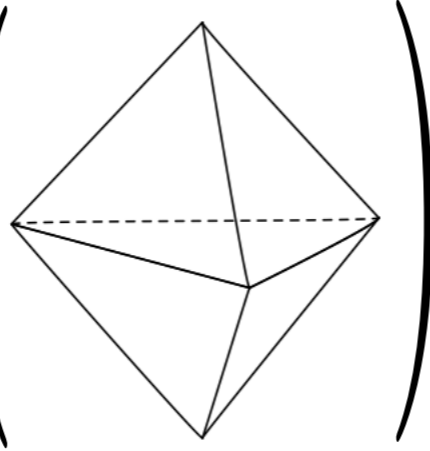

(Dixon and collaborators)

results up to 8-loops

AMPLITUHEDRON

Geometric picture for tree-level amplitudes and loop integrands

(Arkani-Hamed, JT 2013)

$$\mathcal{I}_n^{\ell\text{-loop}} = \Omega \left(\text{Amplituhedron} \right)$$

“Volume”: differential form with logarithmic singularities on the boundaries of the space

Amplituhedron defined by a set of inequalities in the kinematical space

Different ways to express amplitudes (Feynman diagrams, unitarity methods, recursion relations,...) correspond to different triangulations

Dynamics of particle scattering -> **static geometry**

POSITIVE GEOMETRY

Amplituhedron is one example of positive geometries

Geometric picture for ϕ^3 amplitudes - **associahedron**

(Arkani-Hamed, Bai, He, Yan 2017)

Later also generalized to loops - **surfacehedron**

(Arkani-Hamed, Cao, Dong, He, Figueiredo 2023)

hidden zeroes, also for NLSM and other theories

(see talk by Tonnis ter Veldhuis on Tuesday)

More examples of positive geometries: **cosmological correlators**

$\lim_{E_{\text{tot}} \rightarrow 0} \mathcal{C}_n = A_n$ reproduce amplitudes
on the energy poles

Positive geometries seem to be a more
general language for amplitudes

TOWARDS ALL-LOOPS
IN PLANAR $N=4$ SYM THEORY

COLLABORATORS

I will review the progress more broadly but my work is done with

in-progress

MAIN GOAL

Both the integrands and symbols get eventually more complicated at higher loop order -> new ideas needed

We want to calculate amplitudes to all loops: **full non-perturbative result** (no non-perturbative effects in this theory)

We have indirect evidence some simplicity must be there

- ❖ calculation of the amplitude at strong coupling from AdS/CFT
- ❖ integrability predicts the **gamma cusp**

↓
exponentiation of IR divergencies

$$\ln \mathcal{M}_n = \frac{\gamma_{\text{cusp}}}{\epsilon^2} + \dots$$

(in dim-reg)

conjectured to all loops but can not be derived from amplitudes

AMPLITUDE LOGARITHM

Instead of the amplitude, we consider a logarithm for 4pt amplitude

$$\ln \mathcal{M}_4 = \frac{\gamma_{\text{cusp}}}{\epsilon^2} + \dots \leftarrow \text{very mildly divergent}$$

$$\gamma_{\text{cusp}} = \underbrace{4g^2 - 8\zeta_2 g^4 + \dots}_{\text{weak coupling}} = 2g \underbrace{- \frac{3 \log 2}{2\pi} + \dots}_{\text{strong coupling}}$$

$$\ln \mathcal{M}_4 = \sum_{\ell=0}^{\infty} g^{2\ell} \widetilde{M}_4^{\ell\text{-loop}} \quad \text{integrand for the logarithm} \quad \widetilde{M}_4^{\ell\text{-loop}} = \int d^{4\ell} L \widetilde{\mathcal{I}}_4^{\ell\text{-loop}}$$

Integrate over all loops except one: **IR finite function**

$$\mathcal{F}_\ell(z) = \int d^{4(\ell-1)} L \widetilde{\mathcal{I}}_4^{\ell\text{-loop}} \longrightarrow \mathcal{F}(g, z) = \sum_{\ell=0}^{\infty} g^{2\ell} F_\ell(z)$$

amplitude-like function of one kinematical variable

contains the last unintegrated loop

AMPLITUDE LOGARITHM

Fortunately, there is an Amplituhedron also for the logarithm

geometric definition for the integrand $\tilde{\mathcal{I}}_4^{\ell-\text{loop}}$

Triangulate the geometry and find $\tilde{\mathcal{I}}_4^{\ell-\text{loop}}$ **too difficult**

Integrate the object to get $\mathcal{F}_\ell(z)$ **too difficult**

Are we completely stuck here?

Can we keep only “simple” terms in the triangulation we can calculate?

Tried before with Feynman diagrams: **ladder resummation**

(Broadhurst, Davydychev 2010)

$$\begin{array}{c} p_2 \\ \diagup \\ \text{---} \\ \diagdown \\ p_1 \end{array} \begin{array}{c} p_3 \\ \diagdown \\ \text{---} \\ \diagup \\ p_4 \end{array} + \begin{array}{c} \diagup \quad \diagdown \\ \text{---} \quad \text{---} \\ \diagdown \quad \diagup \end{array} + \begin{array}{c} \diagup \quad \text{---} \quad \diagdown \\ \text{---} \quad \text{---} \quad \text{---} \\ \diagdown \quad \text{---} \quad \diagup \end{array} + \begin{array}{c} \diagup \quad \text{---} \quad \text{---} \quad \diagdown \\ \text{---} \quad \text{---} \quad \text{---} \quad \text{---} \\ \diagdown \quad \text{---} \quad \text{---} \quad \diagup \end{array} + \dots \sim e^{-g} \quad \text{for } g \gg 1$$

exponentially suppressed vs linear growth

very bad approximation

APPROXIMATION

(Arkani-Hamed, Henn, JT 2021)

We use a specific triangulation in terms of **negative geometries**

only keep simplest pieces

satisfy a differential equation

$$(\partial_z^2 + g^2) \mathcal{F}_{\text{tree}}(g, z) = 0$$

which we can solve

“tree graphs” in the loop space

$$\mathcal{F}_{\text{tree}}(g, z) = \frac{A^2}{g^2} \frac{z^A}{(z^A + 1)^2} \quad \text{where} \quad \frac{A}{2g \cos \frac{\pi A}{2}} = 1$$

Easy to expand at strong coupling:

$$\mathcal{F}_{\text{tree}}(g, z) = -\frac{z}{(1+z)^2} + \mathcal{O}\left(\frac{1}{g}\right)$$

↗ misses the leading term
↘ has 1/g expansion

$$\gamma_{\text{cusp}} \rightarrow \begin{cases} 2g - \frac{3 \log 2}{2\pi} + \dots & \text{exact} \\ \frac{8}{\pi}g - 1 + \dots & \text{our approximation} \end{cases}$$

qualitatively correct behavior at strong coupling

LOOP OF LOOPS EXPANSION

(Brown, Oktem, Paranjape JT 2023)

Systematic expansion in terms of “negative geometries”

Solved for integrands for all one-cycle geometries

still needs to be integrated / find the differential equation

(Brown, Dixon, Oktem, Paranjape, JT in progress)

$$\left(\text{X} \text{---} \bullet \text{---} \bullet \right) = -\frac{1}{12} \left[\pi^2 + \log^2 z \right] \times \left[5\pi^2 + \log^2 z \right] \left. \vphantom{\left(\text{X} \text{---} \bullet \text{---} \bullet \right)} \right\} \begin{array}{l} \text{simple "tree"} \\ \text{geometry} \end{array}$$

$$\left(\text{X} \text{---} \triangle \right) = -\frac{1}{6} \log^4 z + \log^2 z \left[-\frac{2}{3} \text{Li}_2 \left(\frac{1}{z+1} \right) - \frac{2}{3} \text{Li}_2 \left(\frac{z}{z+1} \right) + \frac{\pi^2}{9} \right] \\ + \log z \left[4\text{Li}_3 \left(\frac{z}{z+1} \right) - 4\text{Li}_3 \left(\frac{1}{z+1} \right) \right] - \frac{2}{3} \left[\text{Li}_2 \left(\frac{1}{z+1} \right) + \text{Li}_2 \left(\frac{z}{z+1} \right) - \frac{\pi^2}{6} \right]^2 \\ - \frac{8}{3} \pi^2 \left[\text{Li}_2 \left(\frac{1}{z+1} \right) + \text{Li}_2 \left(\frac{z}{z+1} \right) - \frac{\pi^2}{6} \right] - 8\text{Li}_4 \left(\frac{1}{z+1} \right) - 8\text{Li}_4 \left(\frac{z}{z+1} \right) - \frac{\pi^4}{18} \left. \vphantom{\left(\text{X} \text{---} \triangle \right)} \right\} \begin{array}{l} \text{complicated} \\ \text{"one-loop"} \\ \text{geometry} \end{array}$$

SUMMARY

Huge progress on all fronts of amplitudes field: progress in the loop integrations, applications to gravitational waves and also planar N=4 SYM amplitudes and positive geometries

All-loop resummation: defined an IR finite function containing 4pt scattering amplitudes, used negative geometries to approximate it to all loops -> surprisingly good strong coupling behavior

Future: more orders in loops of loops expansion, geometry at strong coupling? Can we use the same set of ideas for amplitudes in other theories?

Thank you!
