

PSI

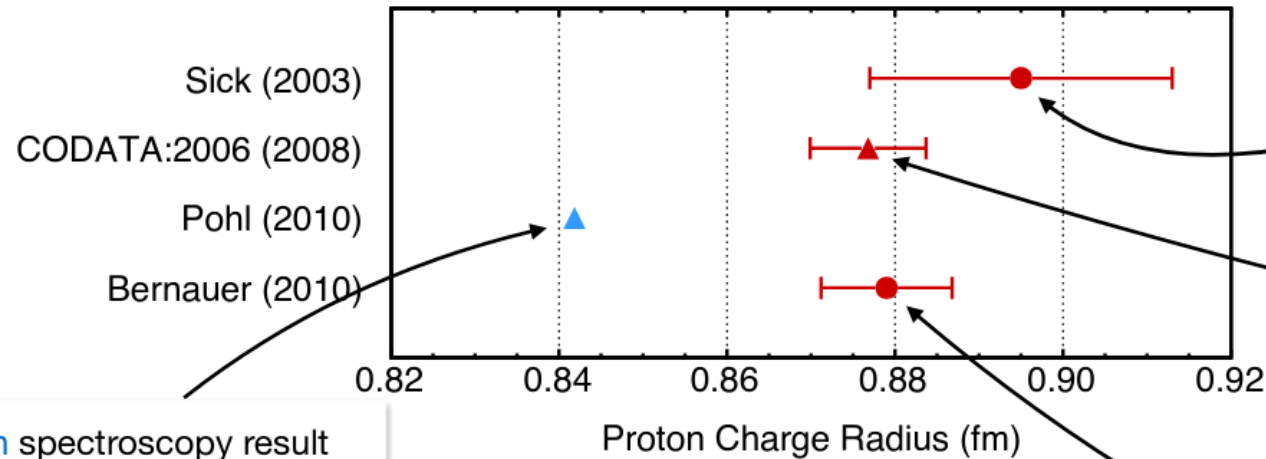

Status of the MUSE experiment

Dr. Tigran Armand Rostomyan :: Scientist :: Paul Scherrer Institute
Yerevan, Armenia, 02.Oct.2024

THE PROTON RADIUS PUZZLE (2010)

Analysis of world **electron-scattering** data

Analysis of **hydrogen spectroscopy** data
Committee on Data for Science and Technology (CODATA)
 $r_p = 0.8768(69)$ fm

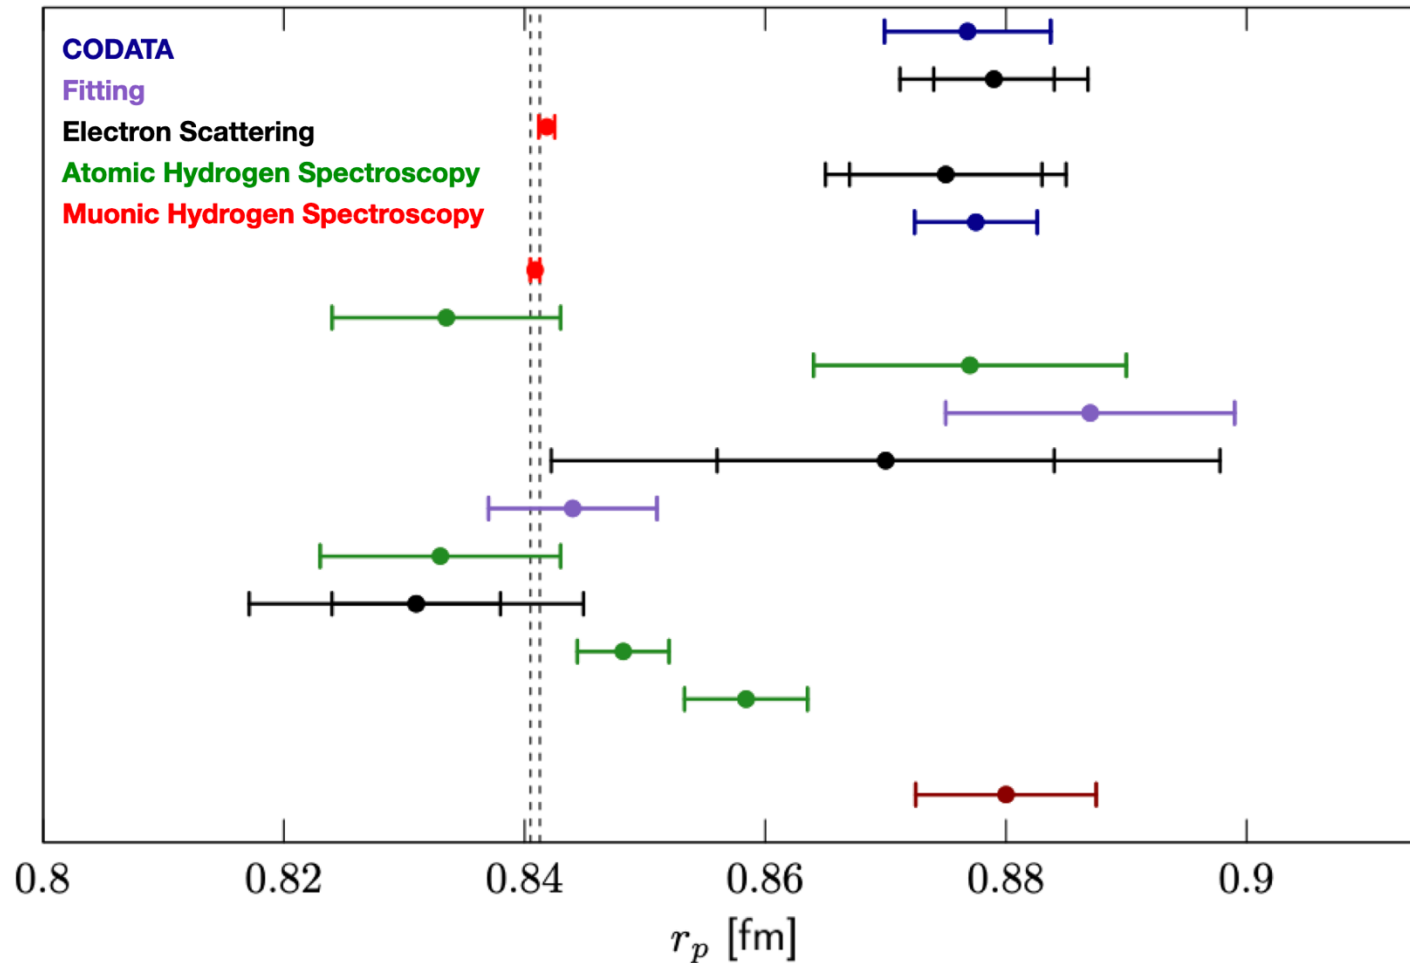

Analysis of MAMI **electron-scattering** experiment

Muonic-hydrogen spectroscopy result
Ten times more precise, but 4% smaller than previously accepted value
 $r_p = 0.84184(67)$ fm

In 2010, the discrepancy between **muonic** and **electronic** measurements of the proton charge radius was a 5σ effect and grew to a 7σ effect in 2013.

I. Sick, PLB 576, 62 (2003); P.J. Mohr et al., Rev. Mod. Phys. 80, 633 (2008); J.C Bernauer et al., PRL 105, 242001 (2010); R. Pohl et al., Nature 466, 213 (2010)

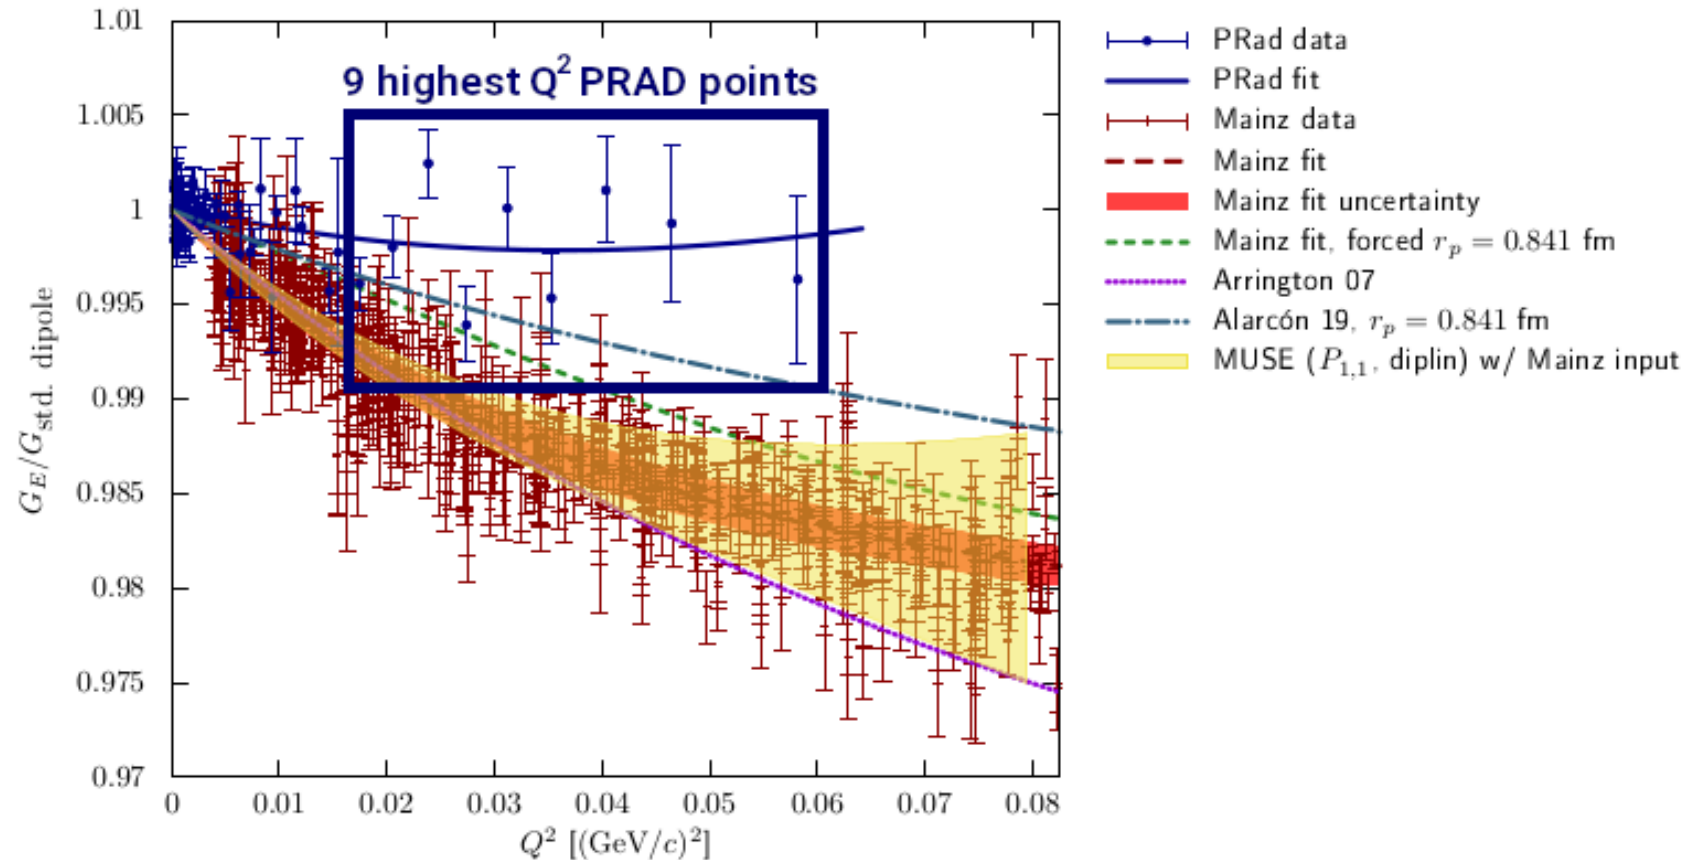

Recent situation

- CODATA'06 (2008)
- Bernauer (2010)
- Pohl (2010)
- Zhan (2011)
- CODATA'10 (2012)
- Antognini (2013)
- Beyer (2017)
- Fleurbaey (2018)
- Sick (2018)
- Mihovilović (2019)
- Alarcón (2019)
- Bezninov (2019)
- Xiong (2019)
- Grinin (2020)
- Brandt (2022)
- MUSE (future) (Arbitrary)

**Newer electronic measurements tend to show a smaller radius
Today some tension between experiments persists...**

Disagreement of different Data

1,5% disagreement between **PRad** highest Q^2 and **Mainz** form factor values leads to **3,0%** discrepancy in cross-sections. According to *Domínguez, Alarcón and Weiss* dispersion + effective field theory calculations (**radius** is treated as a **free parameter**): this discrepancy leads to **~0,04 fm** difference in extraction of the radius.

The MUon proton Scattering Experiment (MUSE)

- ~63 MUSE collaborators from 24 institutions in 5 countries
- Located at the Paul Scherrer Institut in Villigen, Switzerland
- PiM1 beamline: secondary beam with $e^{+/-}$, $\mu^{+/-}$ and $\pi^{+/-}$ at few MHz flux
- Particle species are separated by timing relative to beam RF

Muon Scattering Experiment (MUSE)

Quantity	Coverage
Beam momenta	115, 160, 210 MeV/c
Scattering angle	20 - 100 degrees
Q^2 range for e	0.0016 - 0.0820 GeV ² /c ⁴
Q^2 range for μ	0.0016 - 0.0799 GeV ² /c ⁴

- MUSE will directly compare ep and μp scatterings at sub-percent level precision at 3 different beam momenta in $\pi M1$ area at PSI
- Low Q^2 kinematics for sensitivity to the **proton charge radius**
- Independent and combined determination of the charge form factor and Proton Charge Radius in $e^\pm p$ and $\mu^\pm p$ elastic scatterings \rightarrow tests lepton universality
- With μ^+ , μ^- and e^+ , e^- \rightarrow study Two-Photon Exchange (**TPE**) mechanisms

MUSE Trigger

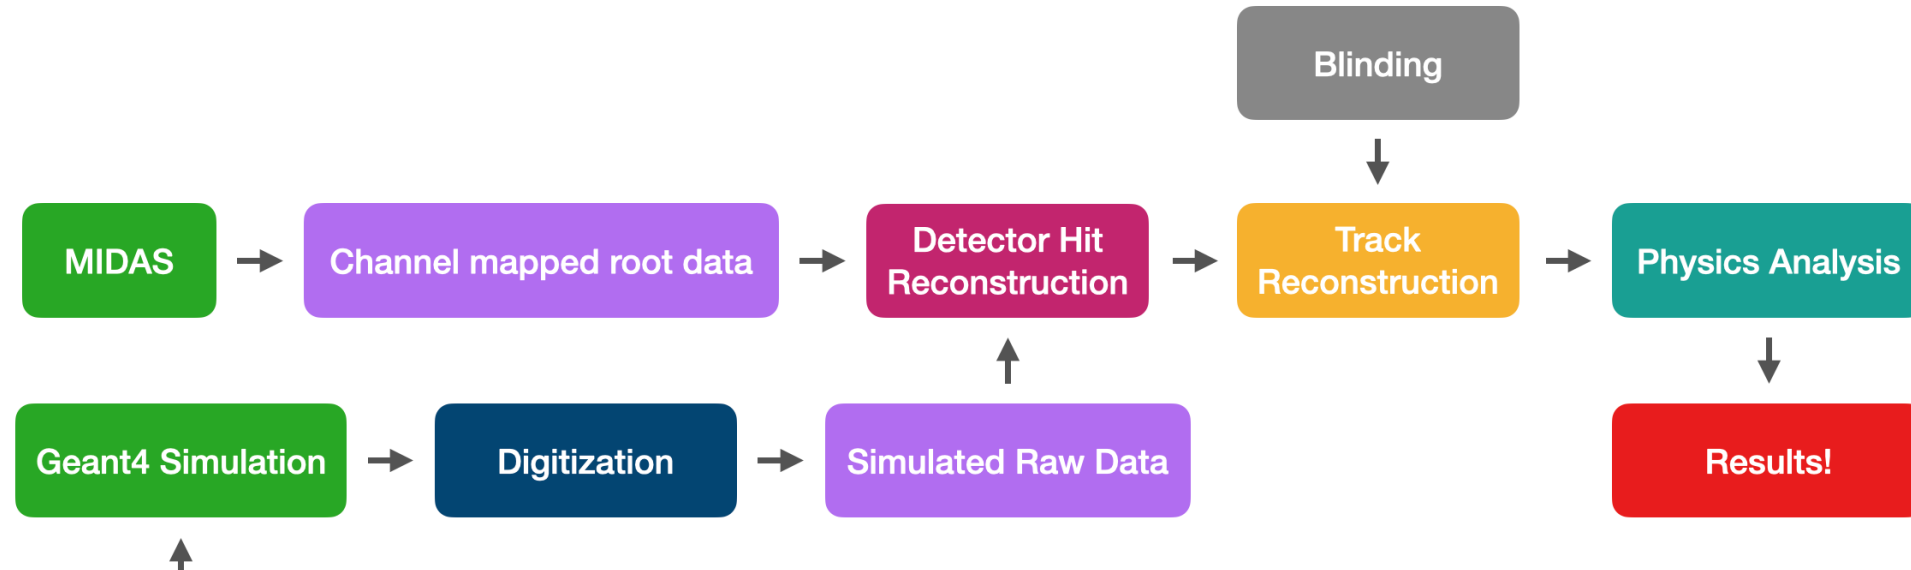

Trigger Logic: TRB3 FPGA-based:

accept e^\pm, μ^\pm , reject π^\pm

(e OR μ) AND (no π) AND (scatter) AND (no veto)

PID is the Hardest Part

MUSE Analysis Diagram

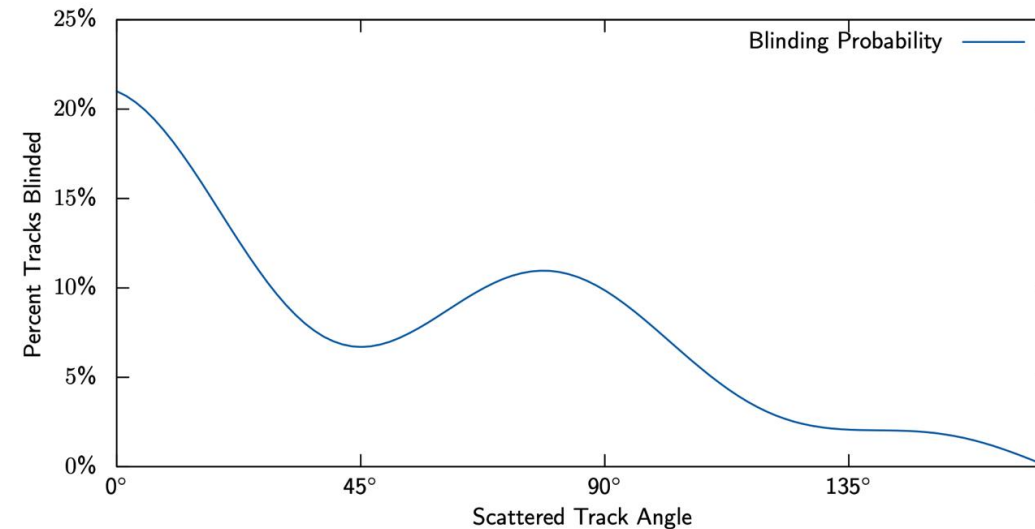

- Analysis done using the COOKER frame work
- ROOT based, used previously in OLYMPUS, TREK, DarkLight
- Decompose analyses into individual modules
 - Low-level: Typically one per detector
 - Mid-level: Tracking, TOF, blinding etc.
 - High-level: Physics analysis

- Fraction of scattered tracks at each angle are stored and hidden for blinding data
- Whether or not a track is blinded is calculated by:

$$P = s \times \frac{3 - \theta}{3}, \text{ where } s = 0.2(A + 0.3\cos(B \times \theta)), \text{ and } A = 0.25 \rightarrow 1, B = 0.25 \rightarrow 1$$

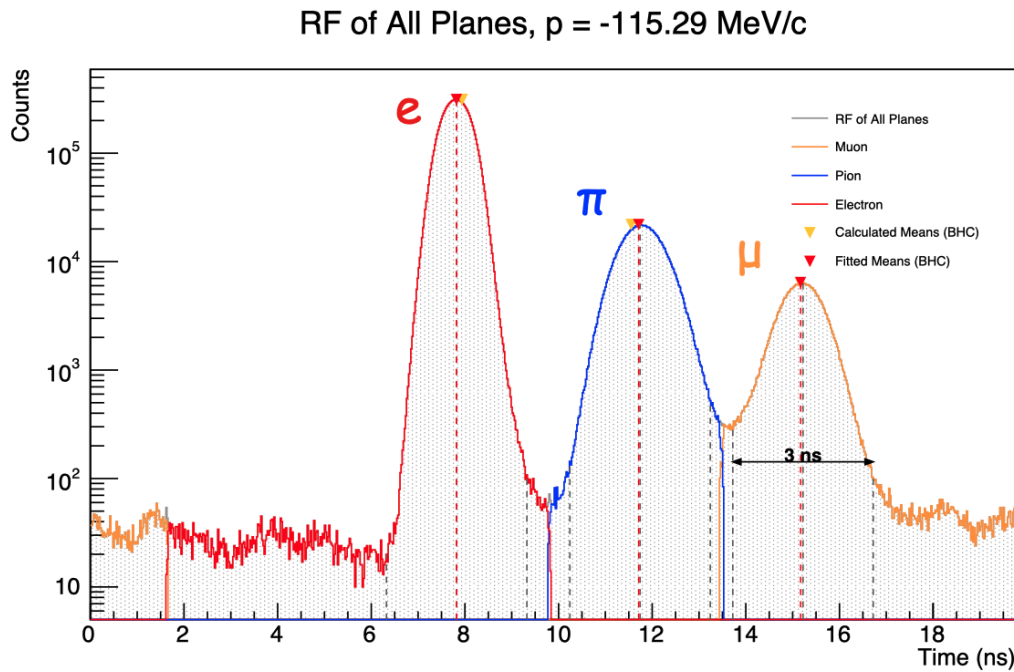

- If $P \geq R$, where R is a uniformly distributed random number between 0 and 1, then the track is blinded
- Can blind up to 25% of tracks at any given angle

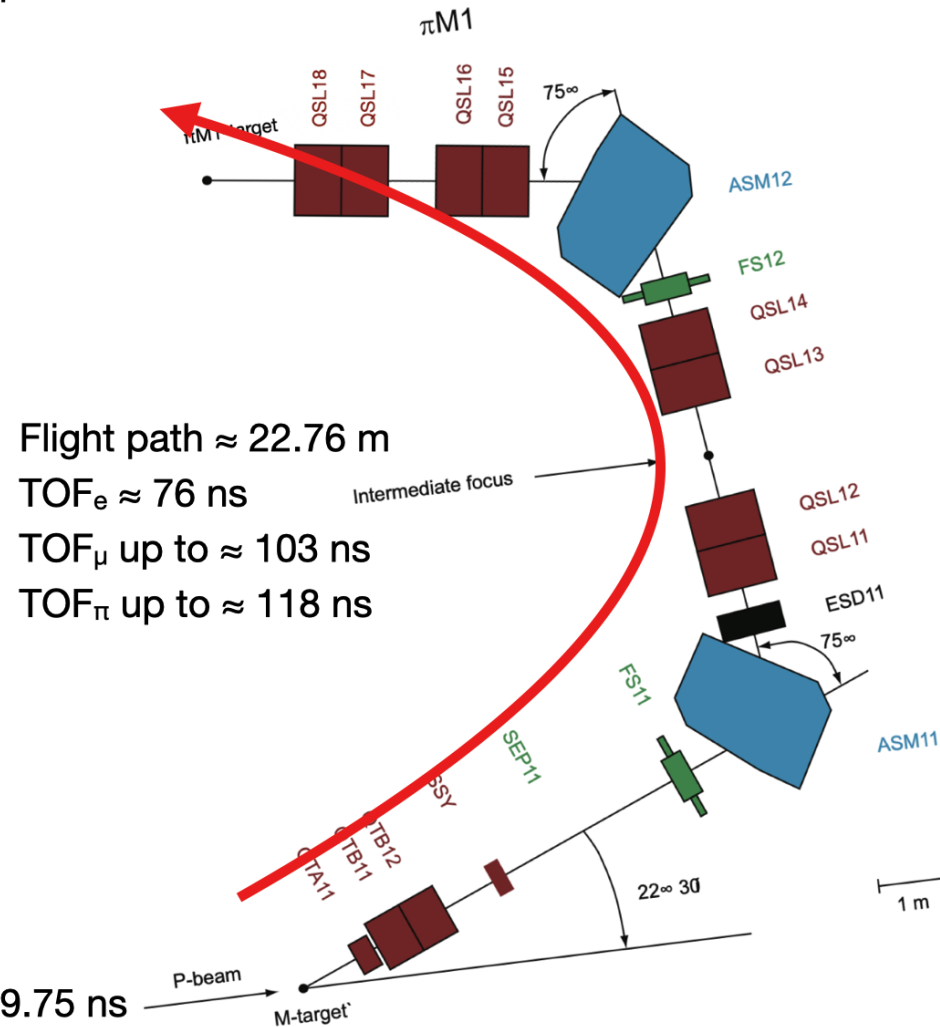

Chance of blinding a track for $A = 0.75$ and $B = 4.2$ as a function of STT angle.

Incoming Particle Identification

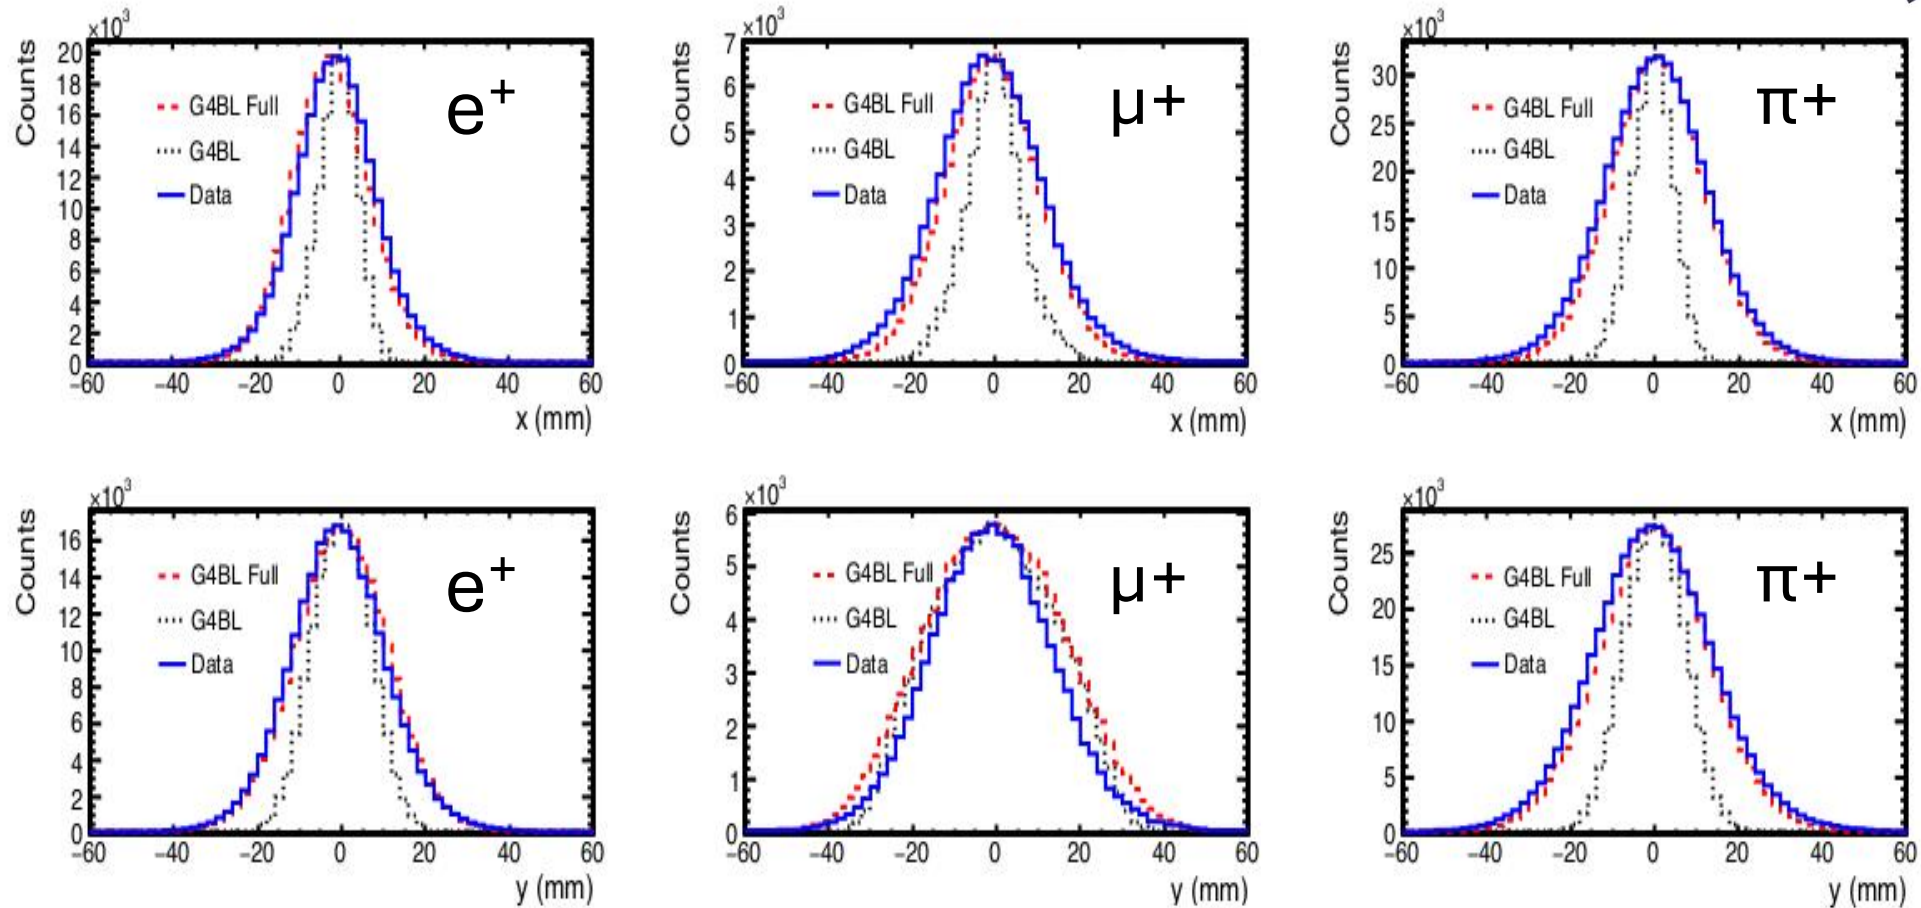

- RF time: time of particles in BH planes relative to accelerator
50.6 MHz RF signal

Proton beam RF 50.6 MHz \rightarrow pulses every 19.75 ns

e^+ , μ^+ , π^+ distributions at +160 MeV/c in π M1

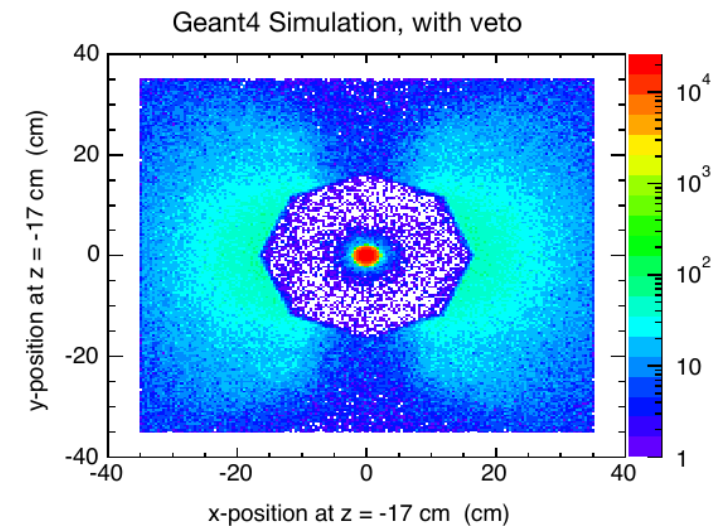

Comparison of data with simulation for different type particle distributions in π M1

- E. Cline et al. (MUSE collaboration). PRC 105, 055201 (2022)

VETO detector

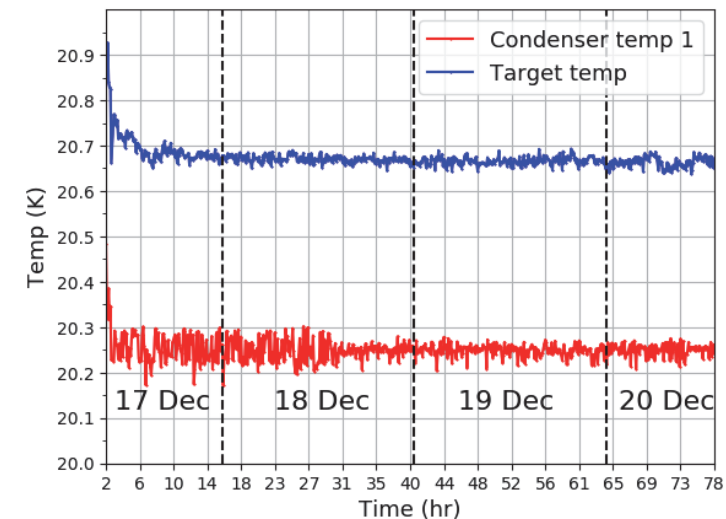

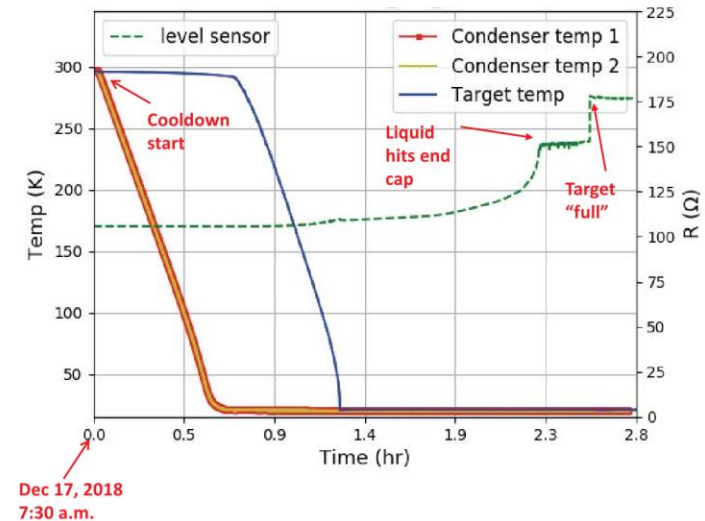

- Annular 4-element, with double PMT read-out, **VETO** detector, surrounding target entrance window
- Eliminates **upstream scattering** and **beam decays** from the data-stream, reduces trigger rate from background events by $\sim 30\%$
- $\sigma_T \leq 200$ ps (**1 ns**); $\varepsilon > 99.0\%$

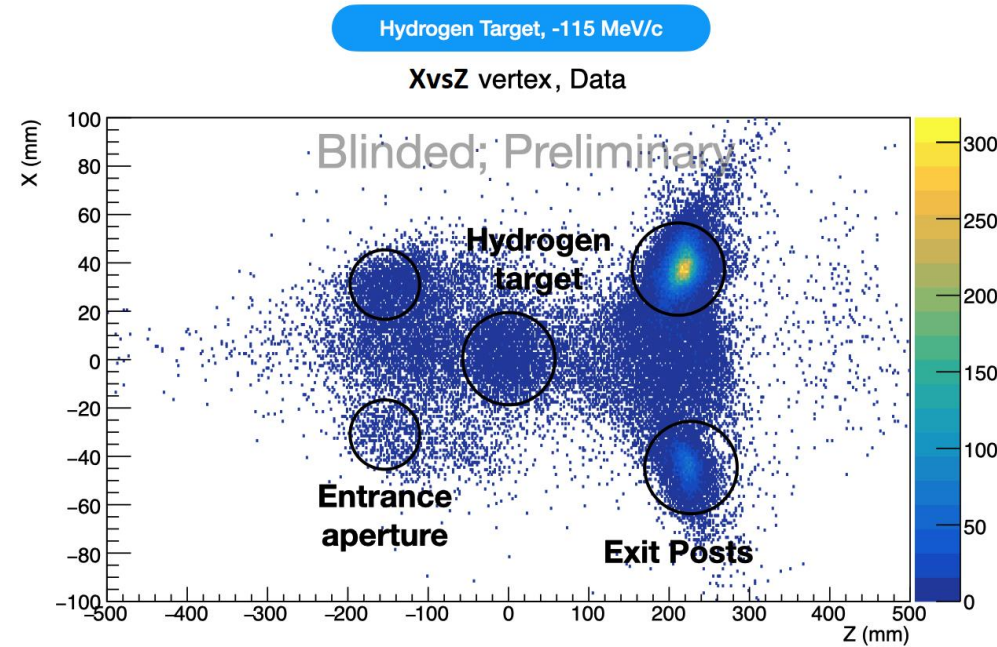

MUSE Liquid Hydrogen Target

- **280 ml LH2 target**
- Target **T = 20.67 K**, stable at $\sigma_T = 0.01$ K level
- **Density = 0.070 g/cm³**, stable at **0.02%** level

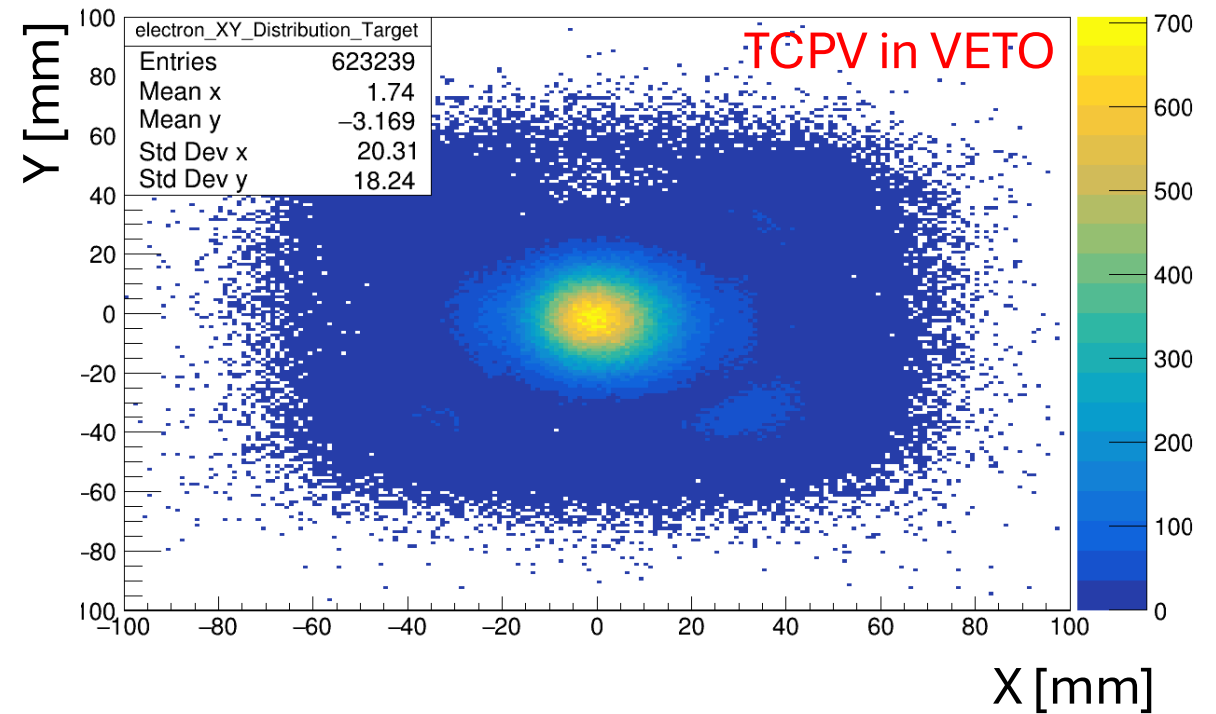

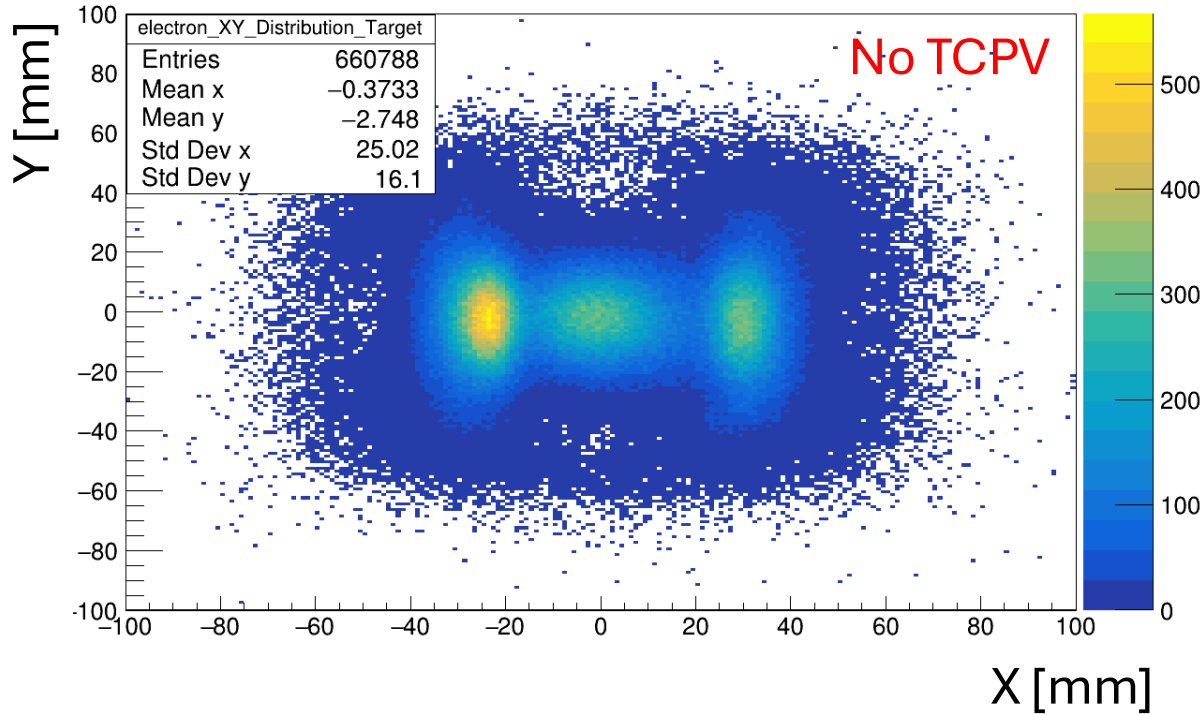

Target Chamber Post Veto (TCPV), Vertex Reconstruction

LH2 target reconstruction for $p = -115 \text{ MeV/c}$

- Large fraction of triggers are background from the target chamber exit posts:
Slows down data taking → increases uncertainties
- TCPV (scintillator with SiPM readout) detector designed and constructed to online veto background events originating from the target chamber exit posts

GEM Tracks at the MUSE Target

- No configuration changes other than TCPV
- Consistent beam rate at -160 MeV/c
- No TCPV vs TCPV in VETO → 48 % trigger rate reduction

TCPV state	MIDAS rate (Hz)	Beam rate (kHz)
No TCPV	2170	1620
TCPV in VETO	1130	1620

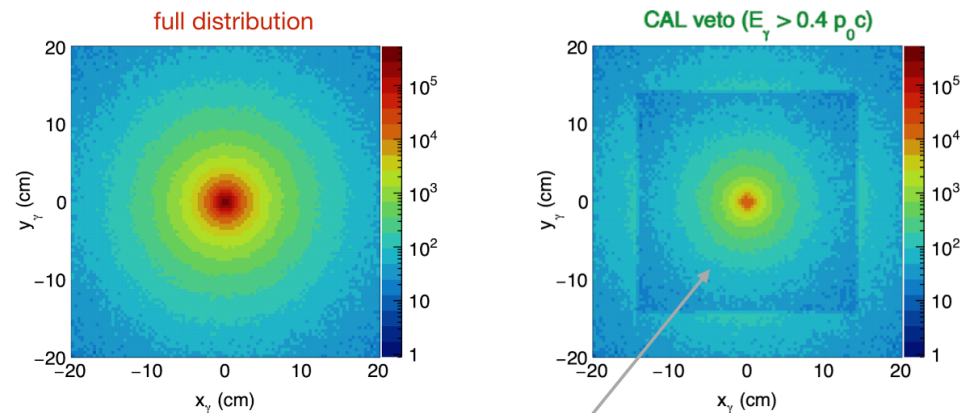

Forward-Angle Calorimeter for MUSE (PSI)

- Calorimeter removes flying forward, high-energy γ from initial-state radiation
- $64 \times (4 \times 4 \times 30) \text{ cm}^3$ Lead-Glass crystals

Simulated downstream photon distribution

$$p_0 = 160 \text{ MeV}/c$$

photons with low reconstructed momentum,
below calorimeter threshold ($\sim 40\%$ of e-beam E)

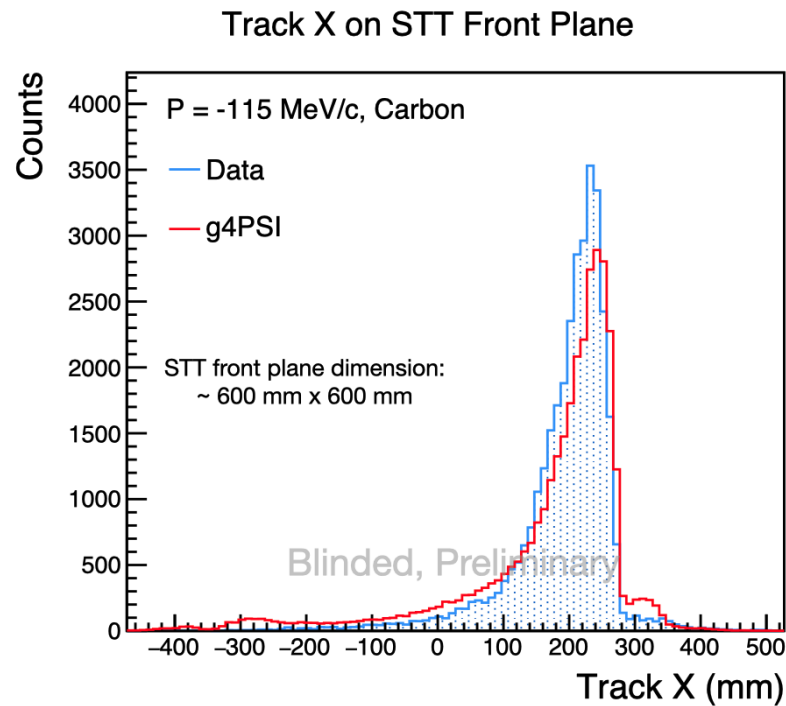

- S. Strauch et al. (MUSE collaboration)
<https://arxiv.org/pdf/2307.06417.pdf>

- W. Lin and T. Rostomyan et al. (MUSE collaboration). Paper in preparation

STT Tracking

- STT has **2. chambers, 5 planes** each in **X and Y**: in total **2850** Straws
- Tracking using “GenFit”; Require hits in at least **3 X**-planes and at least **3 Y**-planes on the same side
- Good agreement between data and simulation for the track position on STT
- Beam is expected to center at about **Y = 0** and **positive X**

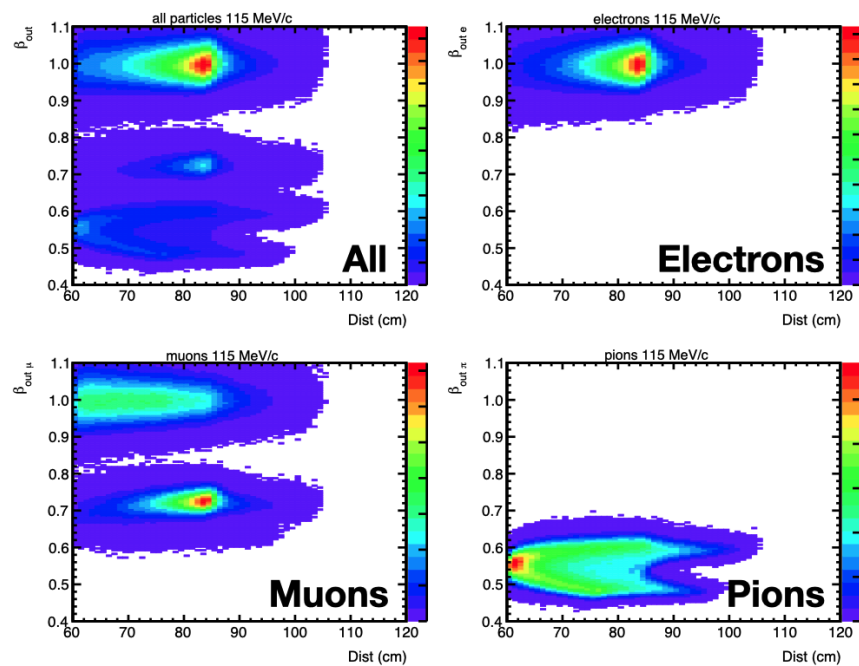

* In STT local coordinates

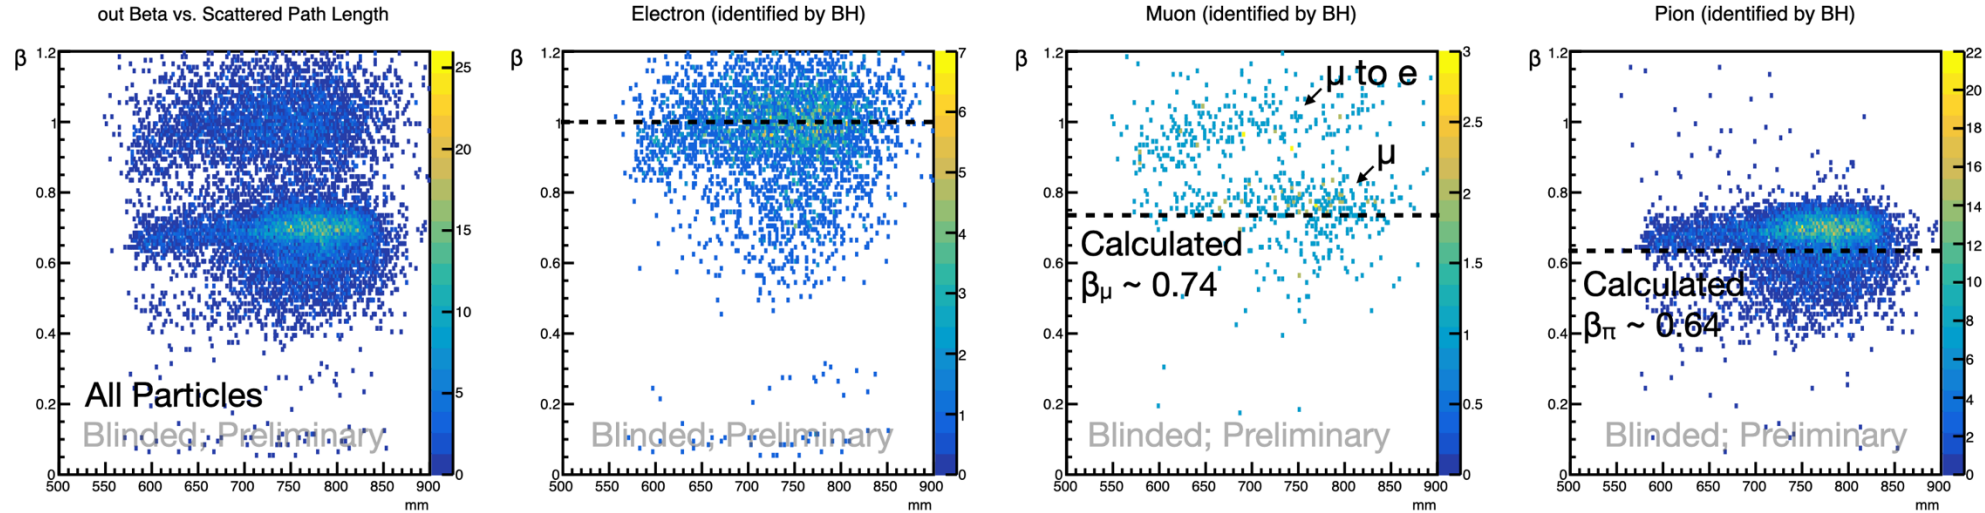

Reaction Identification

- Reaction is identified from the TOF (SPS - BH) and the path length between BH and SPS
- From the track reconstruction, we can get the path length
- Knowing the incoming particle momentum and the TOF, we can find β_{incoming} and β_{outgoing}

Simulation of outgoing Beta vs Scattered Path Length

Reaction Identification

Carbon Target, -115 MeV/c

Momentum of μ from $\pi \rightarrow \mu + \nu_\mu$

β_π and Most probable $\beta_{\text{decay } \mu}$

p	115 MeV/c	160 MeV/c	210 MeV/c
π	0,64	0,75	0,83
decay μ	0,60	0,72	0,82

- β_e is normalised to 1, β_μ is faster than calculated value and β_π is even faster
- Might be due to the time walk;
 $dE/dx(\pi) > dE/dx(\mu) > dE/dx(e)$
- With better walk correction, we will be able to achieve 100 ps / 5 ns \sim 2% for β

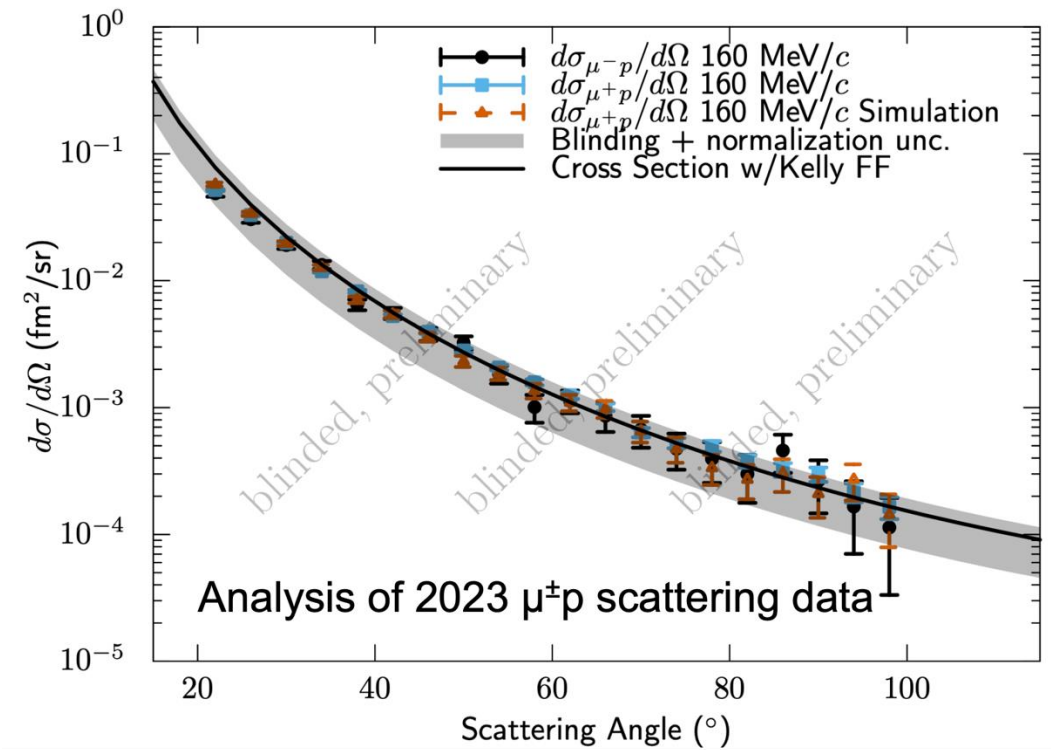

MUSE Pseudo-Data for Cross Section Ratios

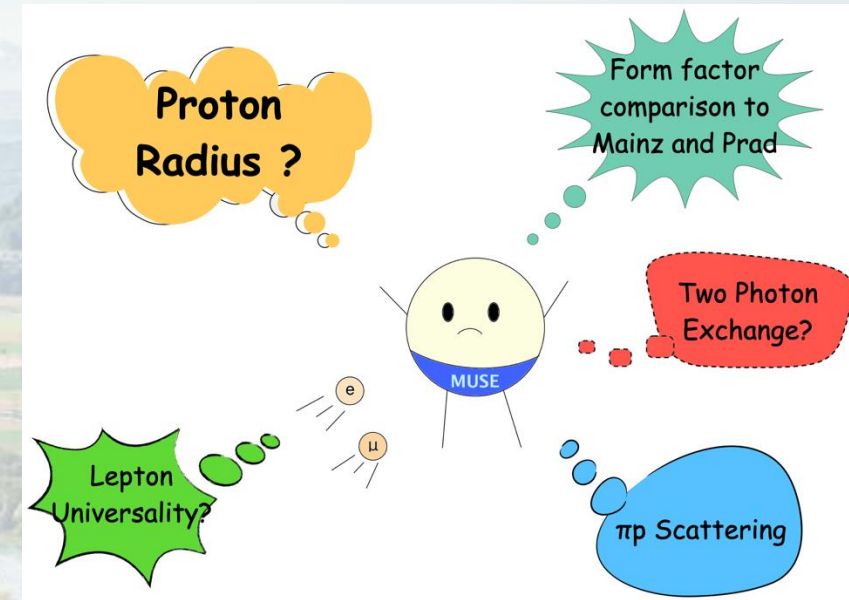

- Projected uncertainties of one full year of scattering data taking
- Estimated how we divided the time, with more time at the highest momentum
- Statistics is based on 2022 data set
- Estimated systematics from the readout rate before TCPV implementation is included
- Take away message: on average we will be able to reach smaller than 1% uncertainties
- More work to be done

Proton form factor, charge radius, two-photon exchange, and lepton universality measurements at Paul Scherrer Institute (PSI) with elastic scattering of 115 – 210 MeV/c e^\pm and μ^\pm from hydrogen

- **2021:** Obtained **first** high statistics scattering data set at ± 115 MeV/c.
- **2022:** Completed 5 months of data taking.
 - Took data in all experimental kinematics on LH_2
- **2023:** Completed 5 months of awarded beam time
- **2024:** completed first half of the 5 months of awarded beam time
 - Collected approximately 50-60 % of expected total statistics
 - Expect to reach 75 % by the end of the year
 - Refining the analysis procedure
- **2025:** Similar 5 months of beam time is expected to complete the data taking

Thank You for Your Attention

MUSE will be the first muon scattering measurement with the required precision to address the Proton Radius Puzzle!

WIR SCHAFFEN WISSEN – HEUTE FÜR MORGEN

E. Cline *et al.*, **Physical Review C 105 (2022) 055201**

Characterization of μ and e beams in the PSI PiM1 channel:

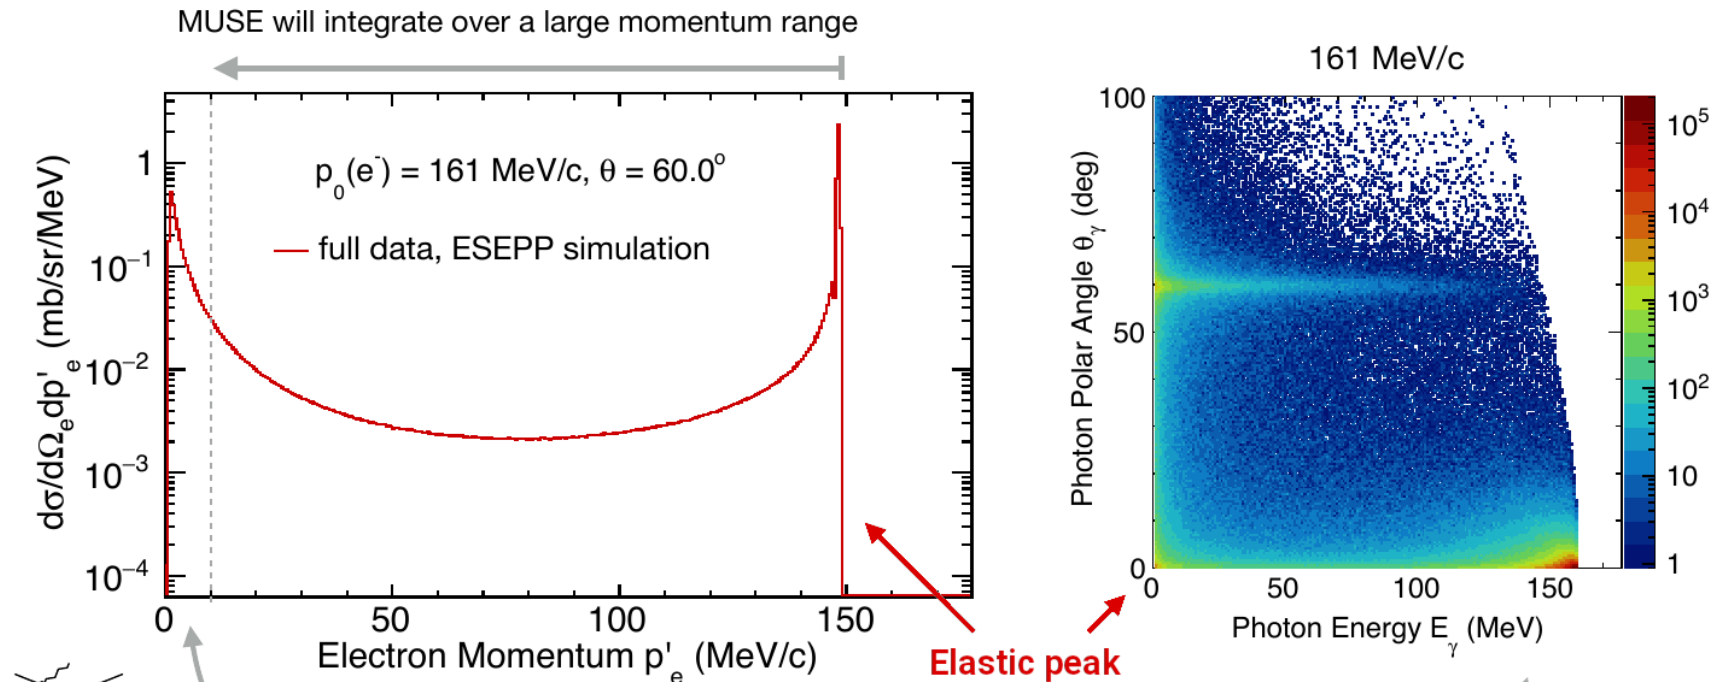

- Average momentum of particles passing through the channel agrees with the central set momentum to within **0.03%**
- The positions of the different particle species were observed to be consistent at roughly **2 mm** level, indicating their momenta are consistent to within approximately **0.02%**
- RF time measurements of particles propagating through the channel showed approximately **0.1%** agreement with the set momentum
- Muon and electron beams have quite similar properties to the pion beam and to each other: knowing p_π or p_μ means we know p_e quite precisely

Radiative Corrections

Radiative Corrections are significant for **e's**.

Greatest sensitivity is to **pre-radiation**. Photon flies forward

$ep \rightarrow e'p\gamma$ **Cross section in MUSE kinematics**

If the incident lepton loses energy due to the emission of a hard photon, then the probability for this lepton to be scattered by the proton increases.

Beam Hodoscope (BH) for MUSE

- BH is most upstream MUSE beam-line detector
- BH is used for beam-particle identification and TOF
- 5 planes built in total
- All time resolutions \rightarrow below 100 ps
- Best achieved time resolution \rightarrow 55 ps

π M1 Beam Profile

Beam X and Y profiles at π M1 obtained with BH live analysis

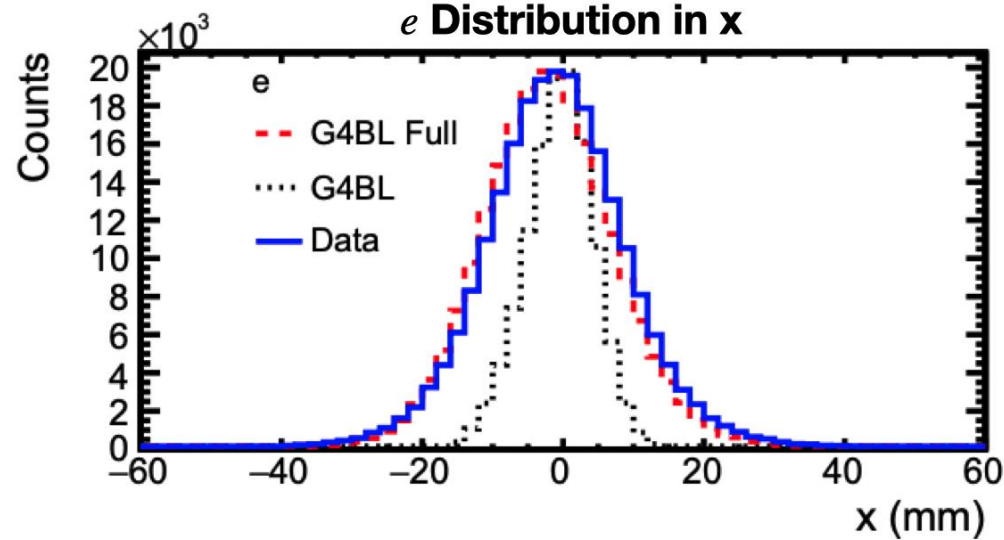

- BHD is 13 paddle plane, with 8 mm wide vertical paddles
- BHC is 16 paddle plane, with 4 and 8 mm wide horizontal paddles

GEM as incident particle tracker

- Incoming beam is tracked by the GEM detectors
- Tracking using “GenFit”; Require hits in at least 2 out of 4 GEM planes
- Particle distribution of the π M1 beam is well understood

Comparison of G4beamline simulations and data at the MUSE target

E. Cline et. al., Phys. Rev. C 105, 055201

Beam Monitor (BM) for MUSE

- BM is installed in the beam-line downstream of the MUSE target
- Is used for TOF from BH to BM for Muon and Pion beam momenta
- Is used for flux determination of un-scattered beam particles downstream the target
- Indicates background events like Møller or Bhabha scattering

Scattered Particle Scintillator (SPS)

- 2 walls on each side of beam. 92 bars, double-ended readout
- Determines **Energy** and **Time** of the scattered off the target particles
- **Muon Decays** in flight can be removed with **TOF** (BH→SPS)

Front wall: 18 bars
(6cm x 3cm x 120cm)

Rear wall: 28 bars
(6cm x 6cm x 220cm)

Peak: particles going through the bar.

Low energy tail: particles going out of the side of the bar

220 cm BC404 bars: $\sigma_{av.} = 52ps \pm 4ps$

120 cm BC404 bars: $\sigma_{av.} = 46ps \pm 4ps$
