

# Electron Spectrometer Measurements and Resolution

AWAKE Collaboration Meeting 11<sup>th</sup> – 13<sup>th</sup> March 2024

<u>F. Pannell</u>, D. Cooke, M. Wing V. Bencini, J. Farmer, S. Mazzoni, C. Pakuza, M. Turner, G. Zevi Della Porta

1

### Overview

### The AWAKE Spectrometer

### Summary of 2023 run

### Preliminary resolution study at CLEAR

Preparing for 2024

### The AWAKE Spectrometer Design and goals

- Separate electrons from proton drive beam
- Introduce a transverse, energy-dependent spatial distribution to accelerated electrons
- Measure intensity of spatially distributed electrons
- Prevent significant beam loss of accelerated electrons prior to measurement
- Provide a sufficient dynamic range of measurable electron energies
- Measure, with sufficient resolution, the energy profile of electron bunch
- Run 2a/b: Demonstrate the ability to measure the emittance of the accelerated electrons (David's talk)

#### **UC**

# The AWAKE Spectrometer

Run 1:

Intensified camera, 17m from screen, light transported through 3 mirrors.

#### The AWAKE Spectrometer **Optics**

'Old spectrometer'

tunnel

#### **Run 1**:

Intensified camera, 17m from screen, light transported through 3 mirrors.

#### **Run 2**:

Addition of camera array for direct imaging. Angled -30° below horizontal to reduce radiation exposure.

dark room Andor iStar 340T Intensified 16-bit CCD Towards intensified 400mm focal length camera Views entire screen

Towards spectrometer

dark room

# The AWAKE Spectrometer

Intensified camera is 16-bit, (relatively) low resolution.

• If a signal is there, we have a better chance of being able to extract it in post-run analysis.

![](_page_5_Picture_5.jpeg)

# The AWAKE Spectrometer

Intensified camera is 16-bit, (relatively) low resolution.

- If a signal is there, we have a better chance of being able to extract it in post-run analysis.
- Camera array is 12-bit, high resolution.
- During <u>live</u> data taking in the run, signals are identified that are not visible on the intensified camera.

When background is high, the camera array is our best chance during the run for locating position of signals.

Event 132 Electron Acceleration

## Summary of 2023 run activities

The focus for 2023 was SM studies with plasma light.

Final week of the October 2023 run (18<sup>th</sup> – 22<sup>nd</sup>), electron measurements were performed in parallel to proton + plasma program.

- RIF scans alongside energy gain
- The effects of density steps on energy gain
- First push for high energy

Served as an opportunity for commissioning and learning ahead of the 2024 program, where energy gain will become a key focus.

![](_page_10_Figure_4.jpeg)

![](_page_11_Picture_1.jpeg)

Overall resolution of the spectrometer has contribution from the optics, and the <u>scintillator</u> <u>screen</u>

Cameras and lenses straightforward to assess resolution

Scintillator resolution requires electron beam tests

![](_page_11_Picture_6.jpeg)

Mitsubishi Chemical, DRZ series Lanex scintillator, Gd2O2S:Tb, 600us decay time

#### Current screen: DRZ-HIGH

Phosphor layer: 145 mg/cm2, relative brightness: 145%

New screen: DRZ-HR

Phosphor layer: 25 mg/cm2, relative brightness: 25%

![](_page_11_Picture_12.jpeg)

![](_page_12_Picture_1.jpeg)

Overall resolution of the spectrometer has contribution from the optics, and the <u>scintillator</u> <u>screen</u>

Cameras and lenses straightforward to assess resolution

Scintillator resolution requires electron beam tests

#### **Point spread function (PSF):**

Requires 'point-like' beam (impractical...)

Resolution: Convolution of input distribution and measured size

#### Edge spread function (ESF):

Requires 'infinitely hard' edge (easier requirement?)

Resolution from spread of light across boundary

![](_page_12_Picture_12.jpeg)

Mitsubishi Chemical, DRZ series Lanex scintillator, Gd2O2S:Tb, 600us decay time

#### Current screen: DRZ-HIGH

Phosphor layer: 145 mg/cm2, relative brightness: 145%

#### New screen: DRZ-HR

Phosphor layer: 25 mg/cm2, relative brightness: 25%

![](_page_12_Picture_18.jpeg)

Investigate both methods in a (brief) preliminary study... see what we can learn!

![](_page_13_Picture_1.jpeg)

#### Point spread function experiment

![](_page_13_Picture_4.jpeg)

Achieving 'micro' beams:

Experiment at the end of the CLEAR line.

Defocusing in the quadrupole triplet allows for stronger focusing in the final quadrupole doublet.

![](_page_14_Picture_1.jpeg)

#### Point spread function experiment

![](_page_14_Picture_4.jpeg)

Achieving 'micro' beams:

Experiment at the end of the CLEAR line.

Defocusing in the quadrupole triplet allows for stronger focusing in the final quadrupole doublet.

YAG, as the highest resolution screen available, was used as the reference measurement Smallest obtained beam size was 50um (in air, measured on YAG) Camera imaging from slight horizontal offset

- Clear of beam path and minimal perspective distortion
- High resolution lens contribution to spread from optics negligible ( $\sigma < 10um$  in the lab at minimum working dist.)

### **UCL**

### Preliminary resolution study at CLEAR Point spread function experiment

100 images acquired for each, size fluctuation minimal, position jitter non-negligible  $\rightarrow$  fit sizes individually Assuming Gaussian for now, as deconvolution is more straight-forward

![](_page_15_Figure_4.jpeg)

#### Edge spread function experiment

Attempt to create a 'step' by blocking out a portion of the beam

Diverging beam  $\rightarrow$  limit the portion of the phase space entering the block / crossing the boundary

Beam size limitation removed, but possibility for other contributions to spread  $\rightarrow$  investigate

![](_page_16_Figure_7.jpeg)

### Preliminary resolution study at CLEAR Edge spread function experiment

![](_page_19_Figure_3.jpeg)

### Preliminary resolution study at CLEAR Edge spread function experiment

Important that we align the electron trajectory parallel to the block.

Otherwise we introduce additional spread across the boundary into the blocked region.

Strict time limitation  $\rightarrow$ optimised by eye, can be improved with angle scans

![](_page_20_Figure_5.jpeg)

Distance (pixels)

Distance (pixels)

![](_page_22_Picture_1.jpeg)

The edge spread method, under certain assumptions, is a direct measurement of the resolution. Additional spread can come from:

- Angle misalignments between the electrons and the tungsten block
- Halo from scattering with the tungsten
- Portion of the beam phase space crossing the boundary

Simulation and detailed investigation can evaluate these components

- Simulations underway
- Returning to CLEAR for a one week, detailed experiment, this year

These will make the <u>resolution worse</u>, we can think of the edge spread results as 'upper bounds' on the screen resolutions (current screen ~130um, new screen ~70um)

We can cross-check with the PSF results after the upcoming study

![](_page_22_Picture_12.jpeg)

#### **UCL**

## Preparing for 2024

#### Instrumentation upgrades

#### Expanding the camera array from 4 to 7

- Allows us to see the whole screen
- If we aren't sure of the energy, cover ourselves!

#### Installation of high-res translation camera

- Reusing the old spectrometer calibration lamp track
- Mount the camera from above → do not obscure camera array
- If we're limited by pixel size, this camera can recover us.

![](_page_23_Picture_11.jpeg)

![](_page_24_Picture_11.jpeg)

#### Simulations and background

#### Changing the plasma length with laser foils

- 400GeV protons through the foils  $\rightarrow$  background increases
- Quick test with LBDP2 in October confirms this (x ~100)
- Modelling (and removing) background difficulty, but needed

#### Electrons through the foils

- Understanding electron scattering through the foils
- Decisions on where to place them along the vapour source

#### The increased background from protons The scattering of electrons through the foils

![](_page_24_Figure_21.jpeg)

### Thanks!

![](_page_25_Picture_2.jpeg)

![](_page_26_Picture_1.jpeg)

## Backup

![](_page_27_Picture_1.jpeg)

measured size  $^{2} = true size^{2} + resolution^{2}$ 

![](_page_27_Figure_4.jpeg)

**YAG:**  $49.5^2 = true size^2 + 38.4^2 \rightarrow$  True beam size calculated as 31um

**HR:**  $96.6^2 = true size^2 + 69.0^2 \rightarrow$  True beam size calculated as 67.6um

**HIGH:**  $112.5^2 = true size^2 + 126.2^2 \rightarrow$  Calculation fails

It looks like we aren't working with Gaussian beams. Now looking into new convolutions.

![](_page_27_Picture_9.jpeg)

#### Image stitching with the new camera array
