KEK

Introduction

$$pp \rightarrow e^- e^+ jj$$

Events collisions at the LHC are characterized via their features:

- **Global features:**

Kinematics of the hard process as masses, momenta, helicity correlations, etc, encode the global features for the final state particles. Together with the kinematics for the resonantly mediated particles, global features span the entire phase space.

- **Local features:**

Local features are extracted from the properties of the particles confined by the jet boundaries, e.g. momentum of jet constituents, pseudo rapidity of the jet constituents, etc. This information doesn't span the entire phase space and localized inside the jet boundaries

Simulated with Delphes Event display

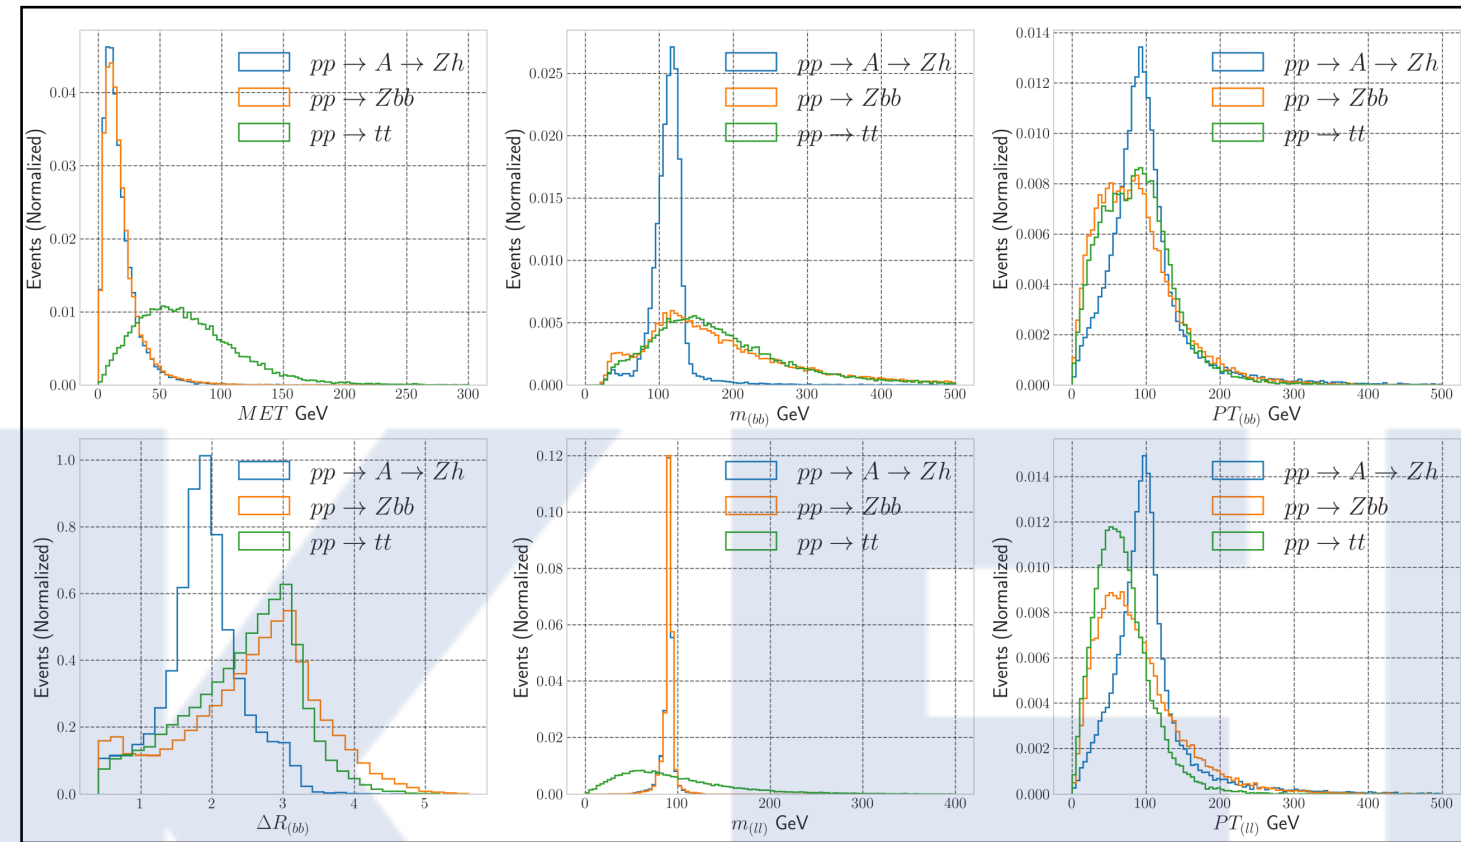

Introduction

For Event classification one can use:

- **Kinematics:**

High-level reconstructed kinematics of the hard process can be used to Classify signal from background events

Arxiv:2305.13781

- **Jet sub-structure:**

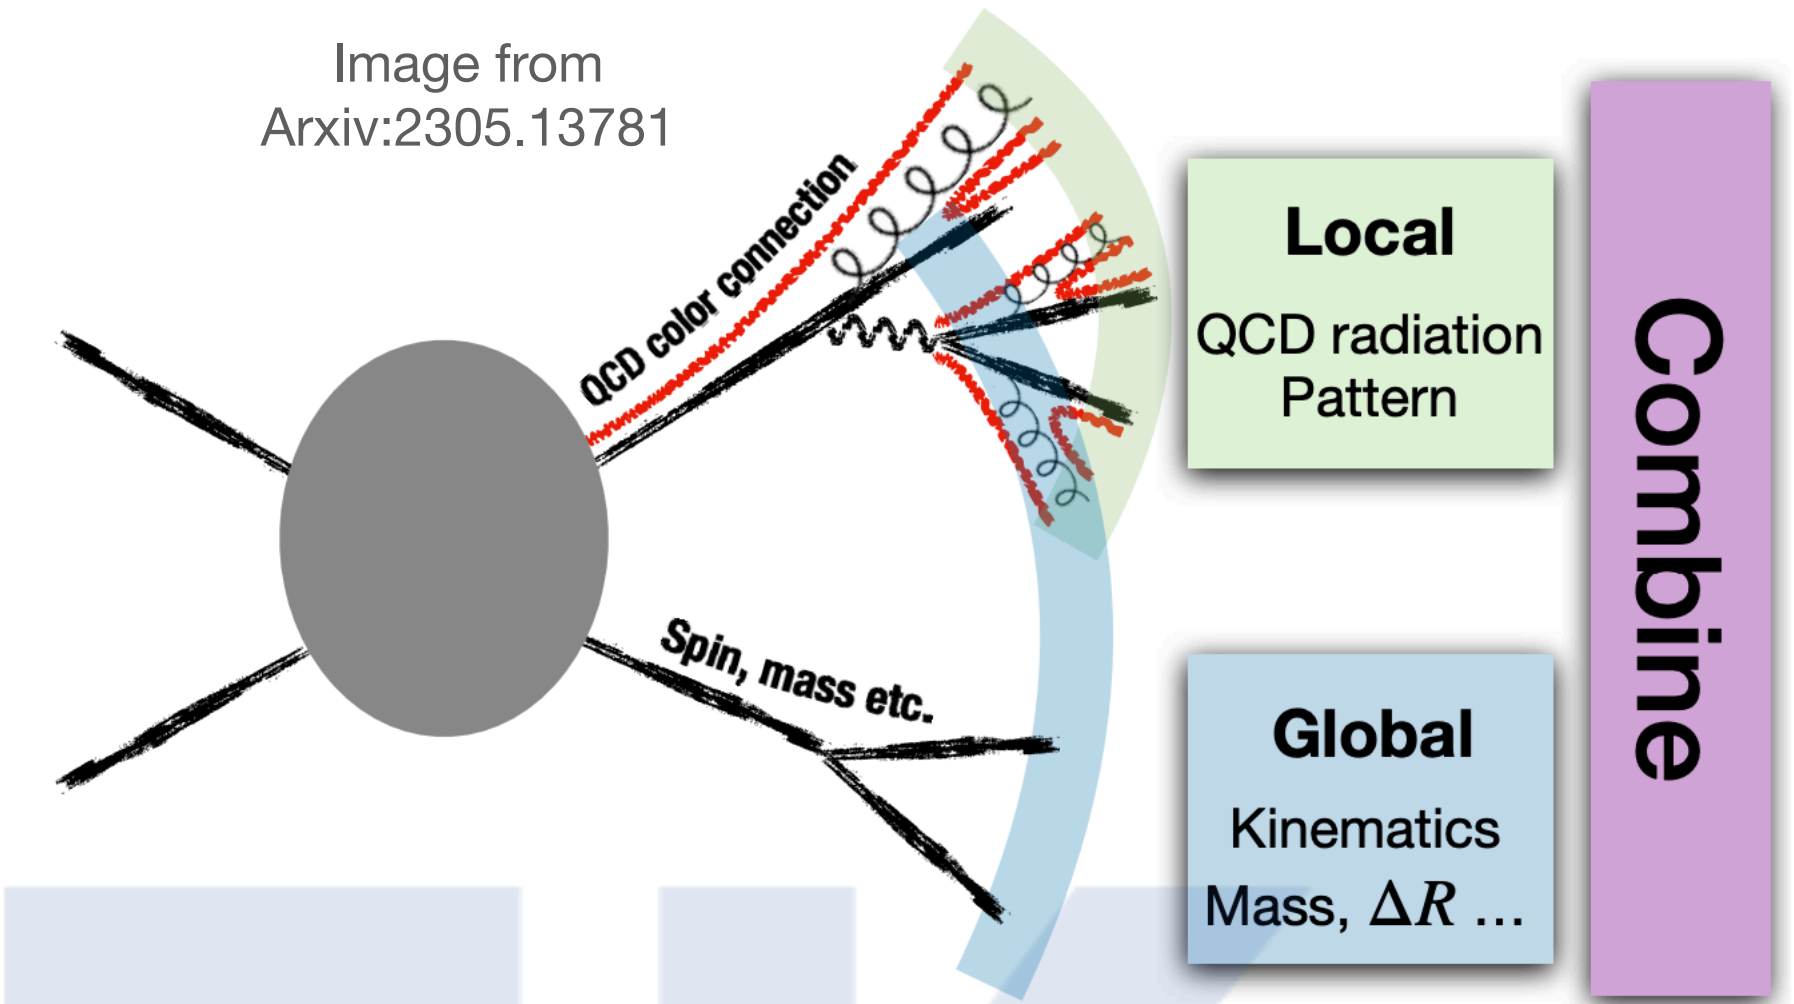

Multi-prong structure of jets can be used for classification. The 3 prong structure of the top jet can be used to distinguish events with top jet from QCD jet processes

Arxiv:1902.09914

Introduction

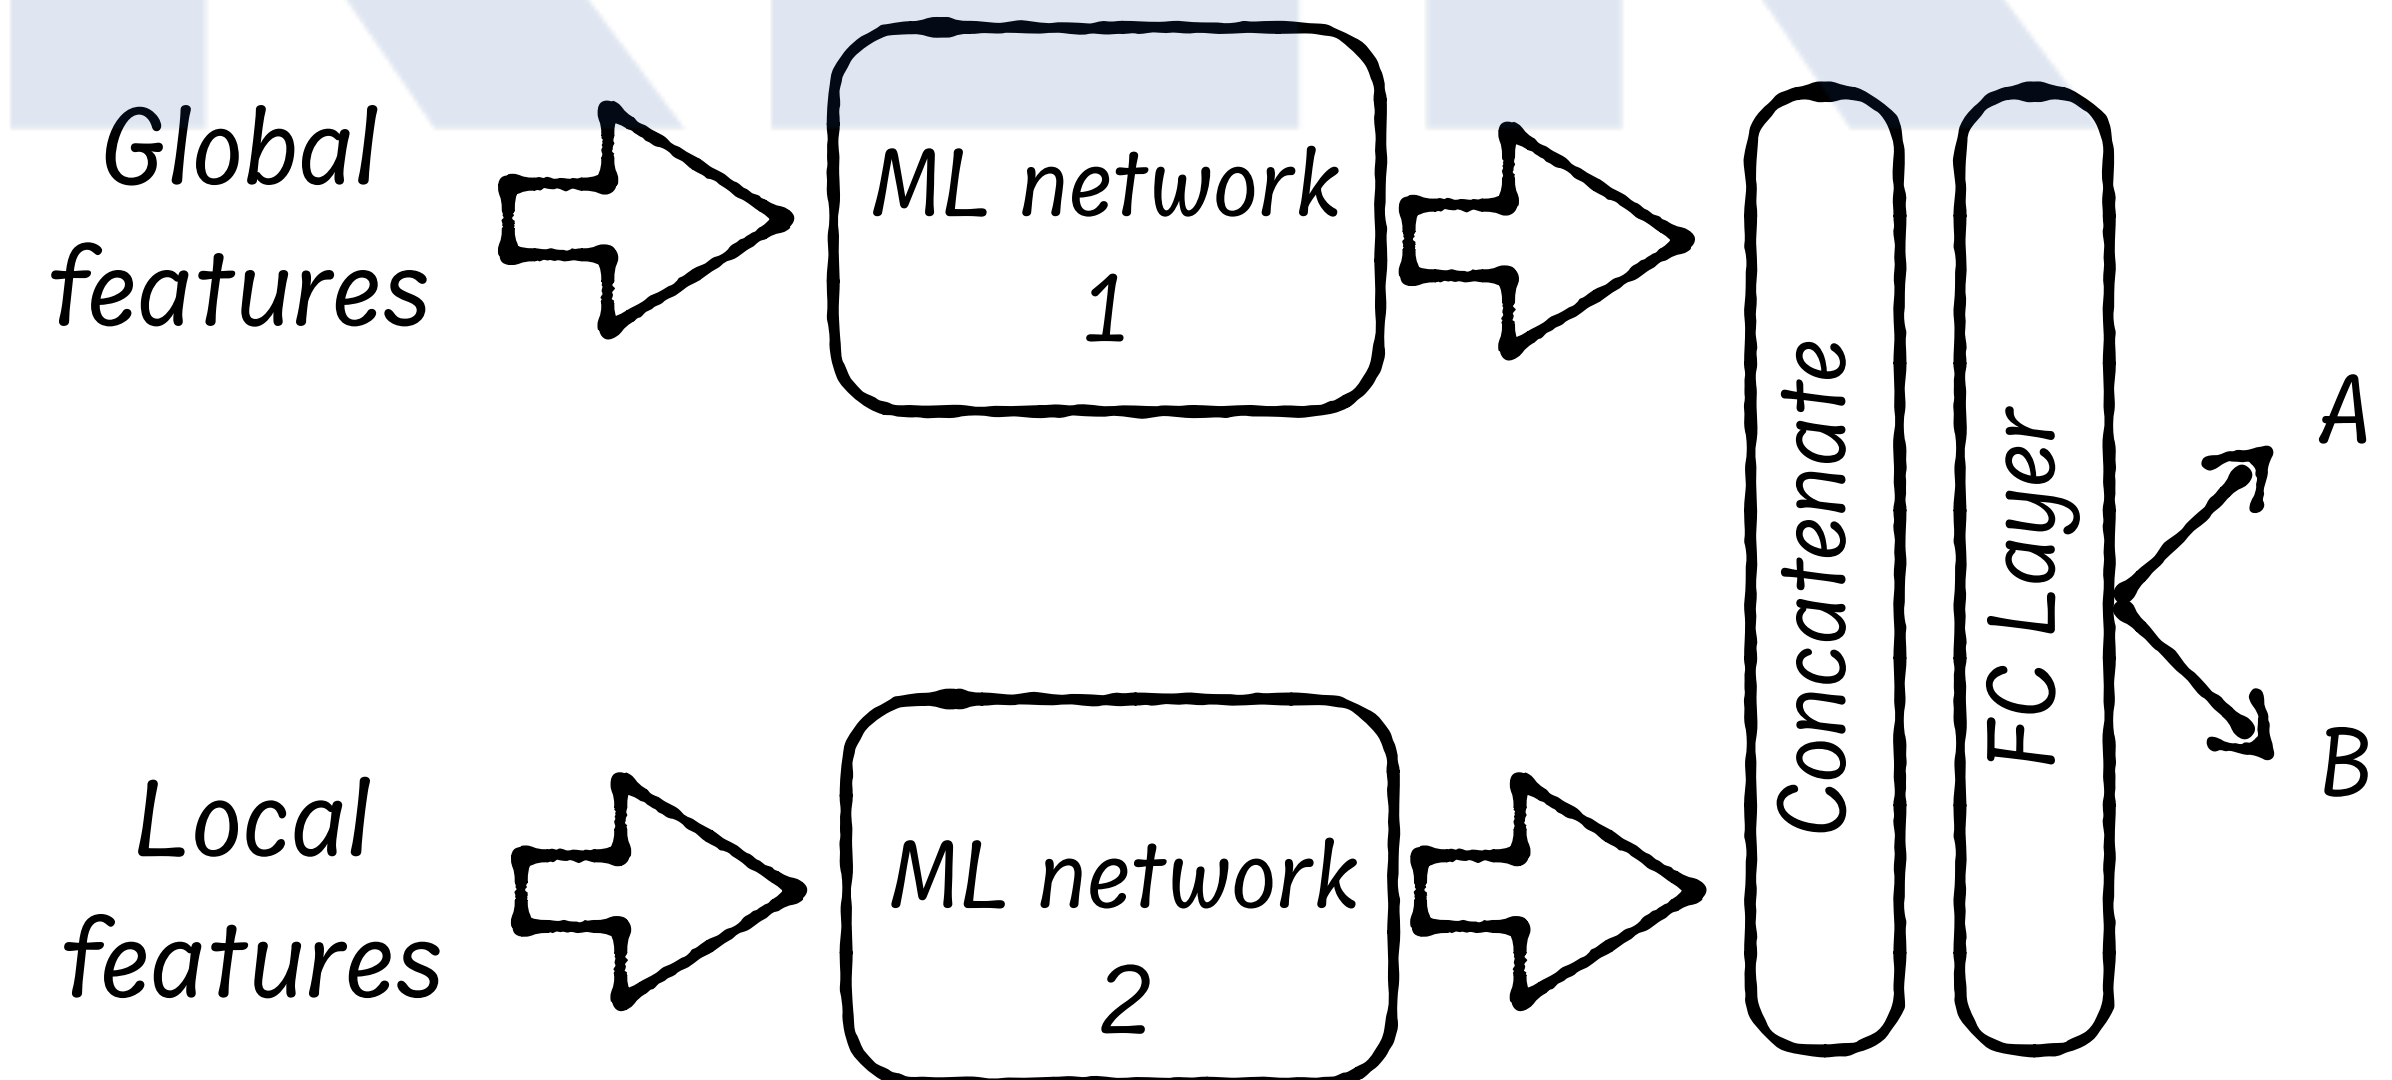

To improve the classification performance we need to use both information in the same time.

Global + local features:

Both local and global information can be feed to multi-modal network with two streams.

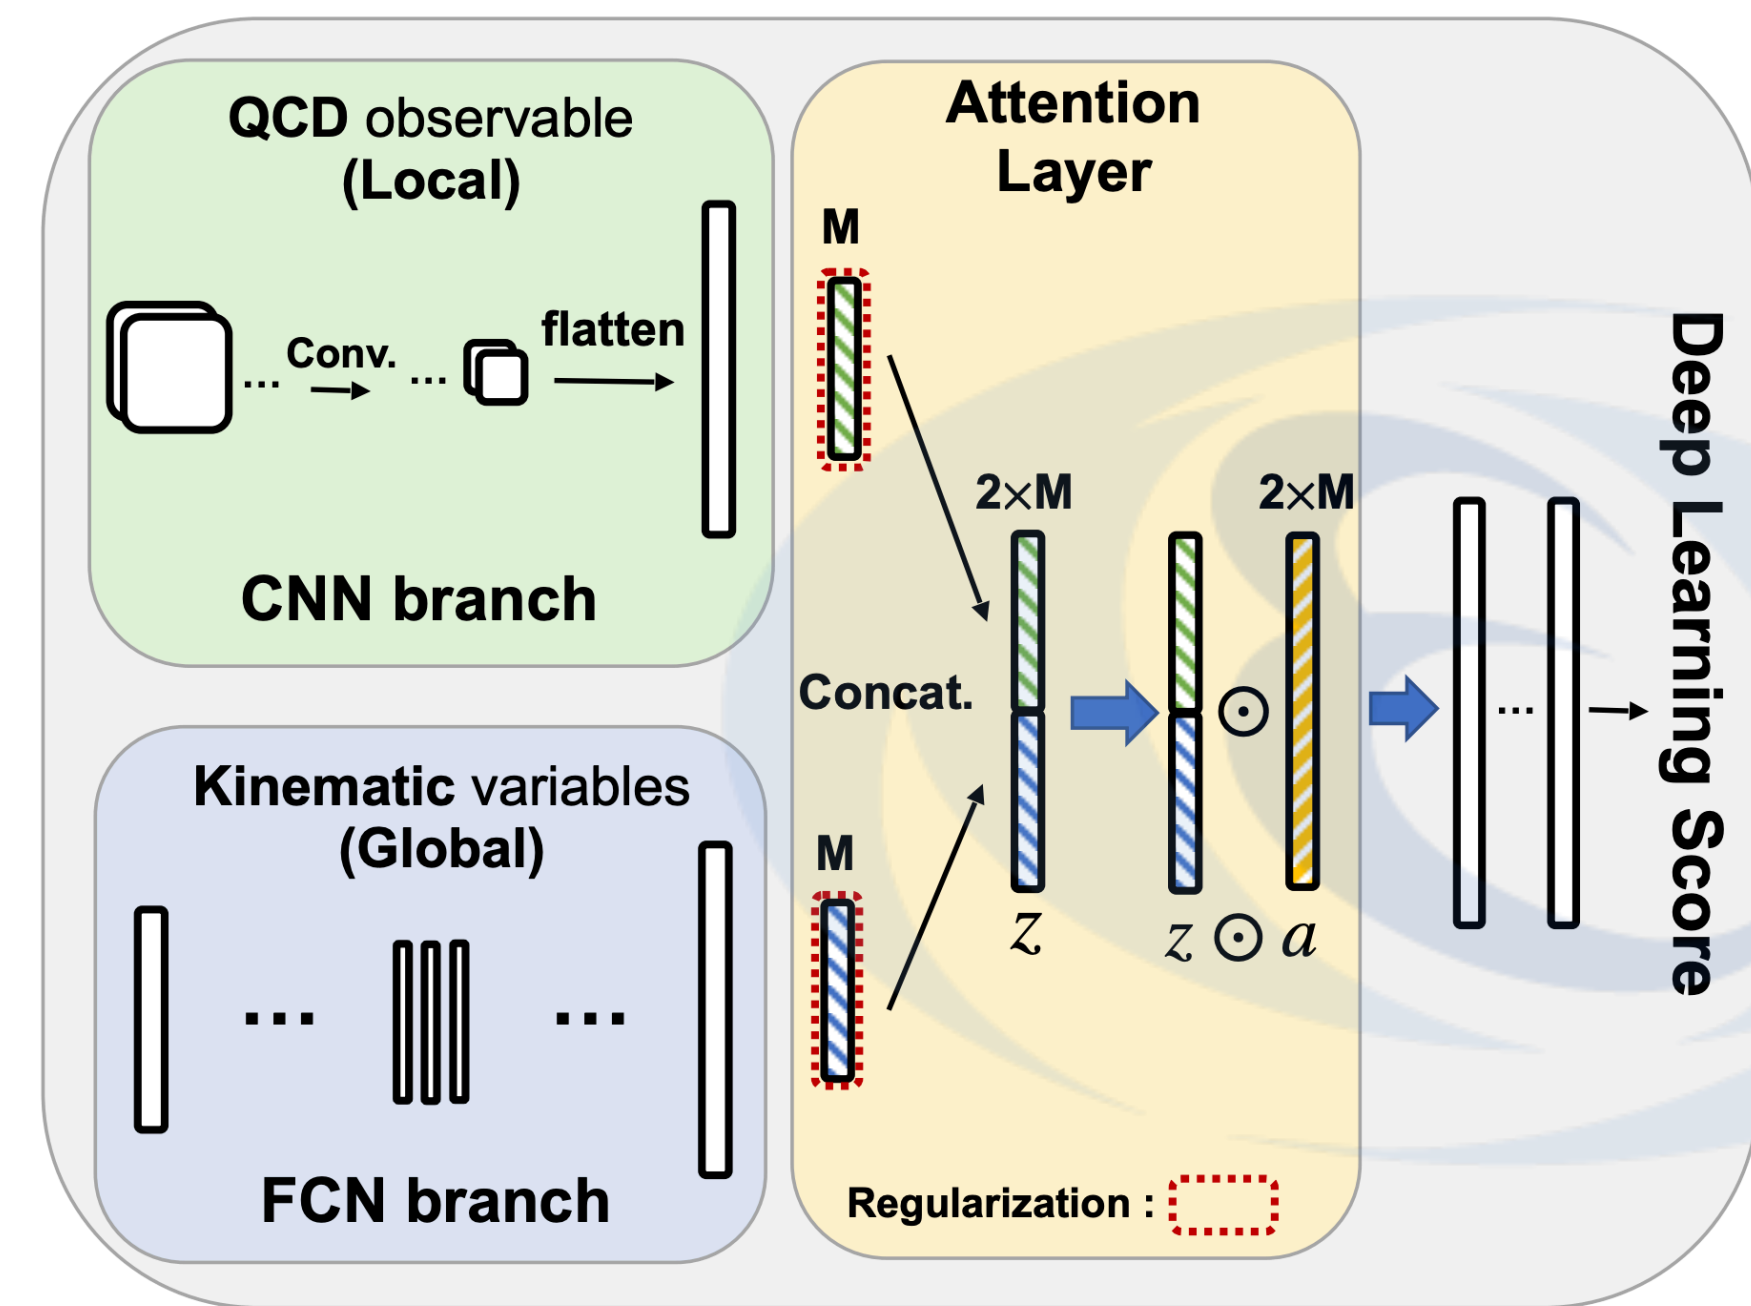

Each network extract the characteristic features of each input data before they concatenated in one dense layer. The concatenated features is then analyzed with one fully connected layer before the output layer.

Introduction

For a simple concatenation the global information encoded by the high level kinematics dominates over the local information. Thus, no much improvement from incorporating the jet information!!

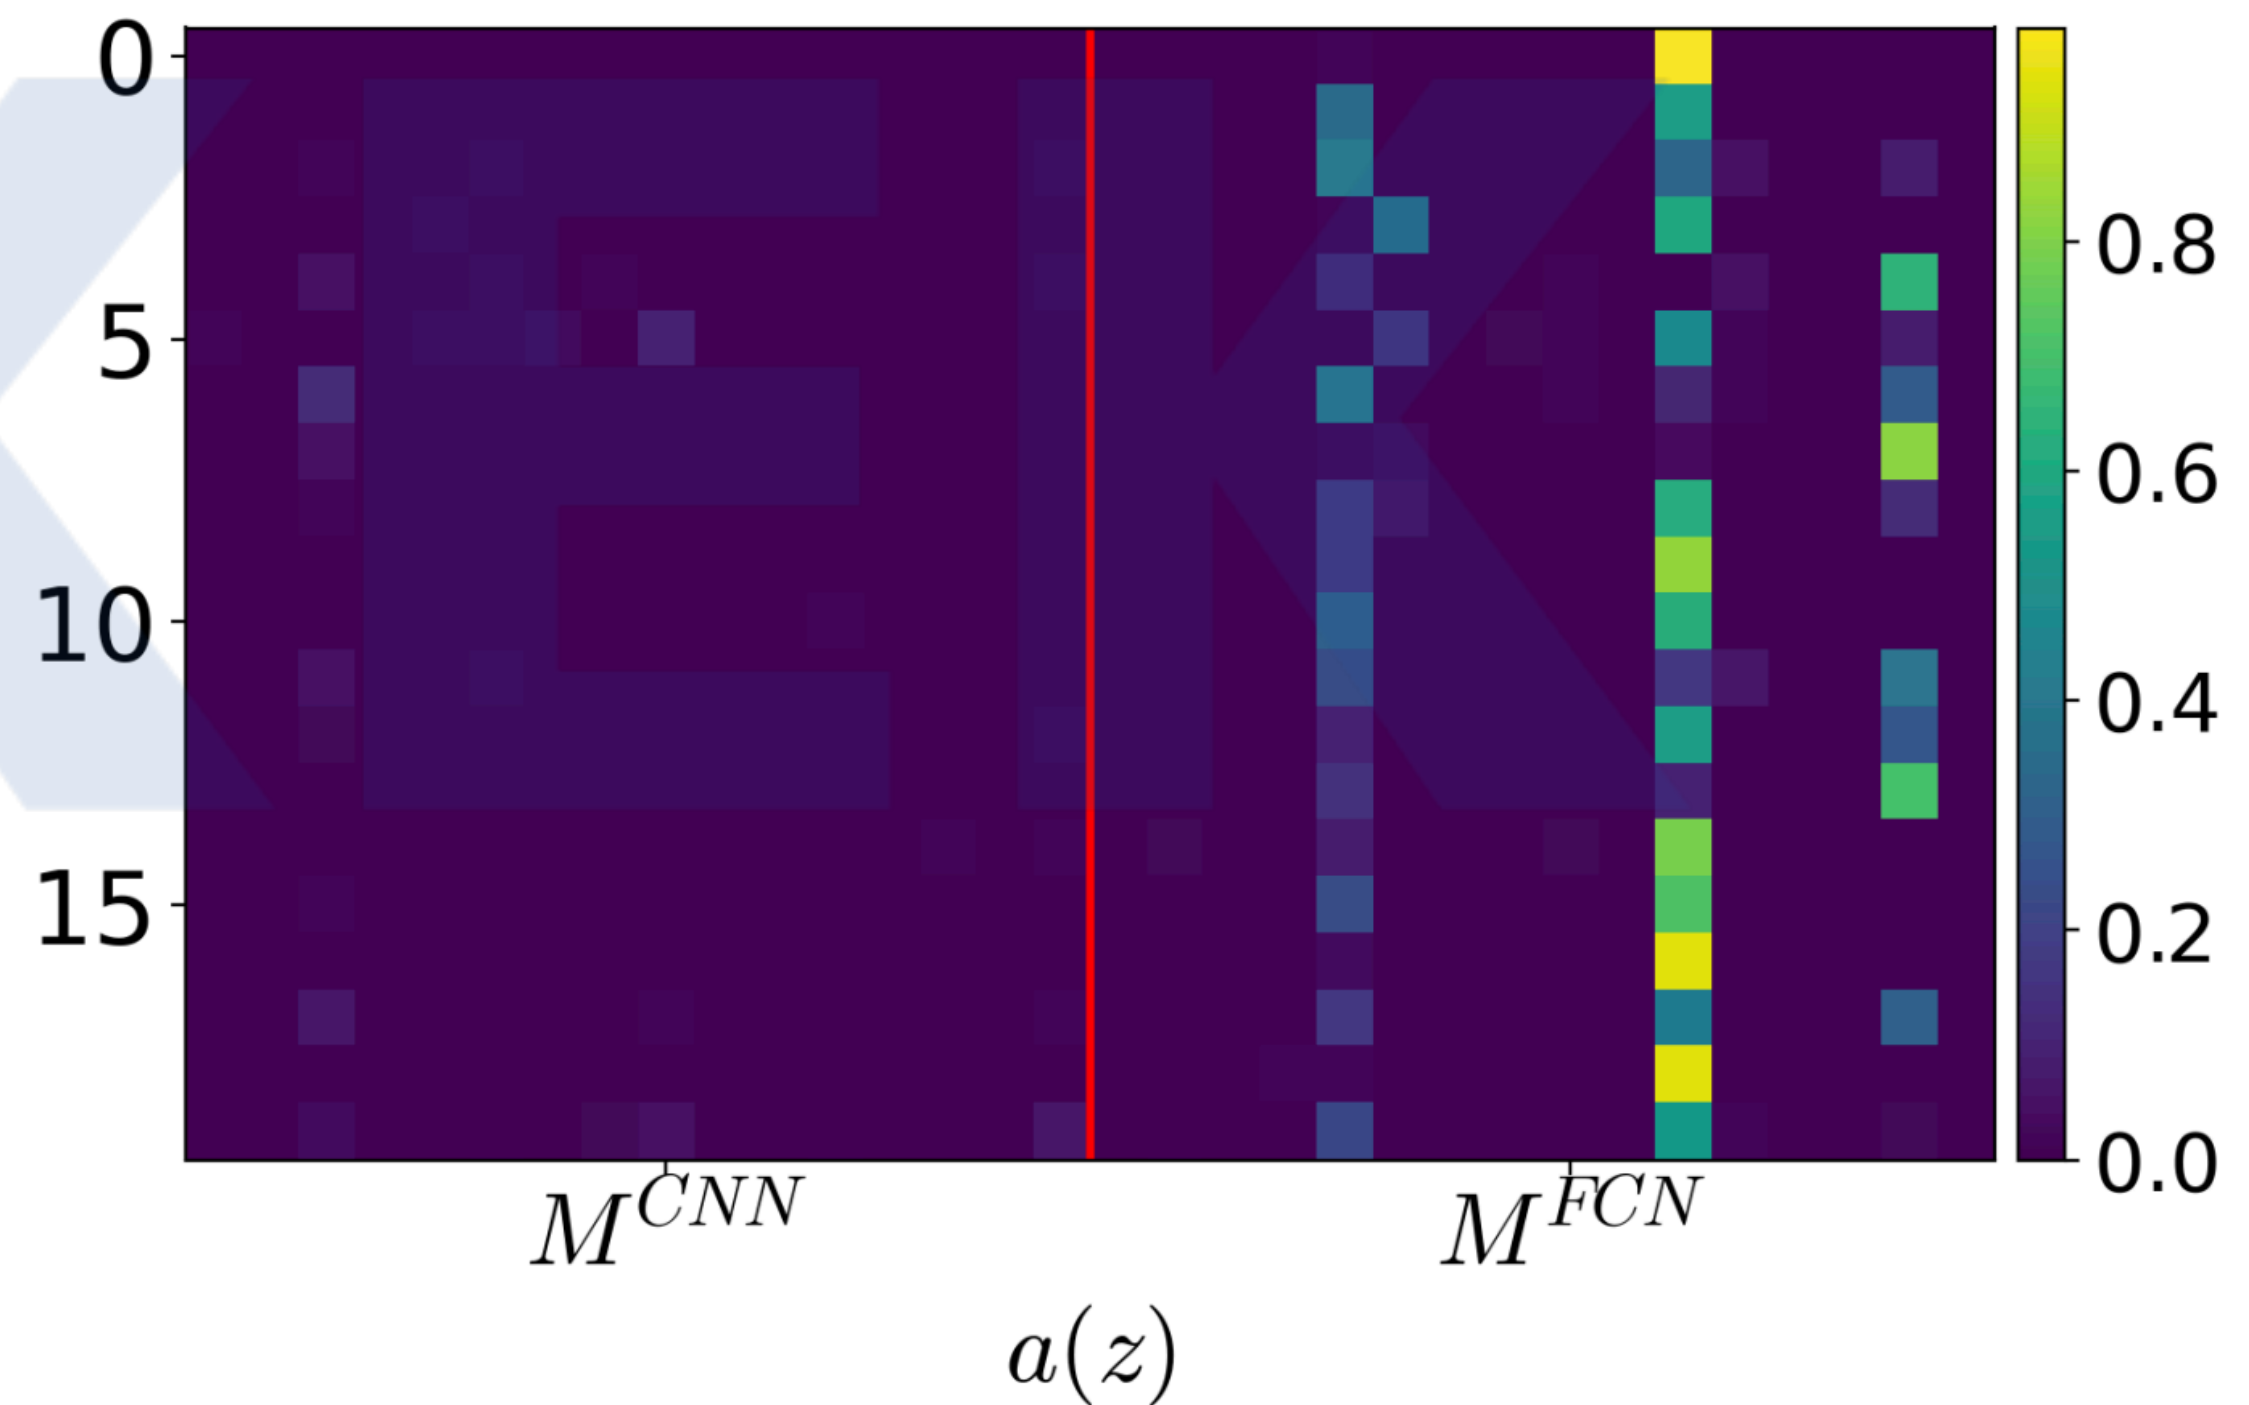

Arxiv:2305.13781

In this paper, the authors used CNN to extract the information from the QCD and MLP to analyze the high level reconstructed kinematics. The output is then concatenated in a single layer, Z .

$z \odot a$ indicates the important information the model focuses on to make predictions

Arxiv:2305.13781

For simple concatenation the model totally ignores the extracted information from the QCD and focuses only on the global information extracted from the kinematics

Transformer Encoders

An alternative way is to use Multi-scale transformer.

But first lets see how the transformer works.

Attention is all you need

A Vaswani, N Shazeer, N Parmar, J Uszkoreit, L Jones, AN Gomez, Ł Kaiser, I Polosukhin
Advances in neural information processing systems, 2017 · proceedings.neurips.cc

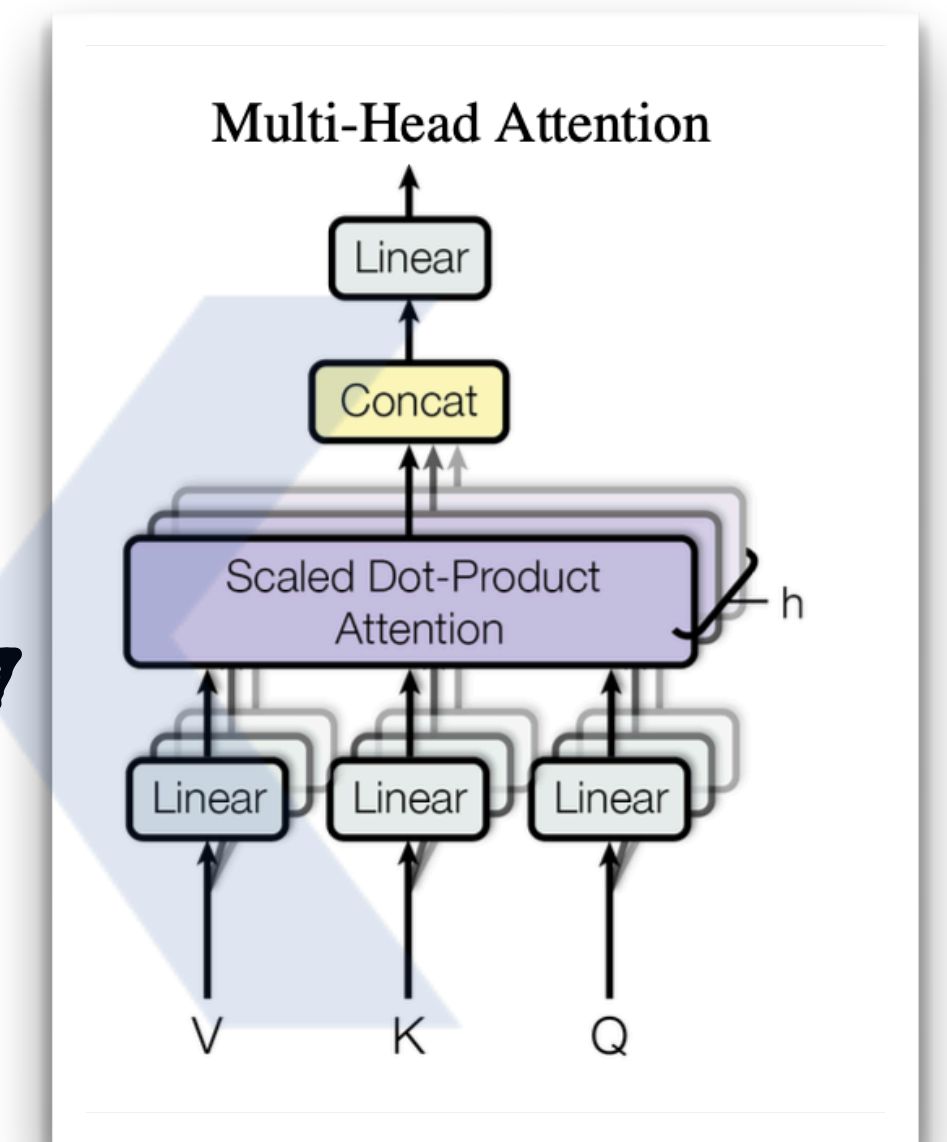

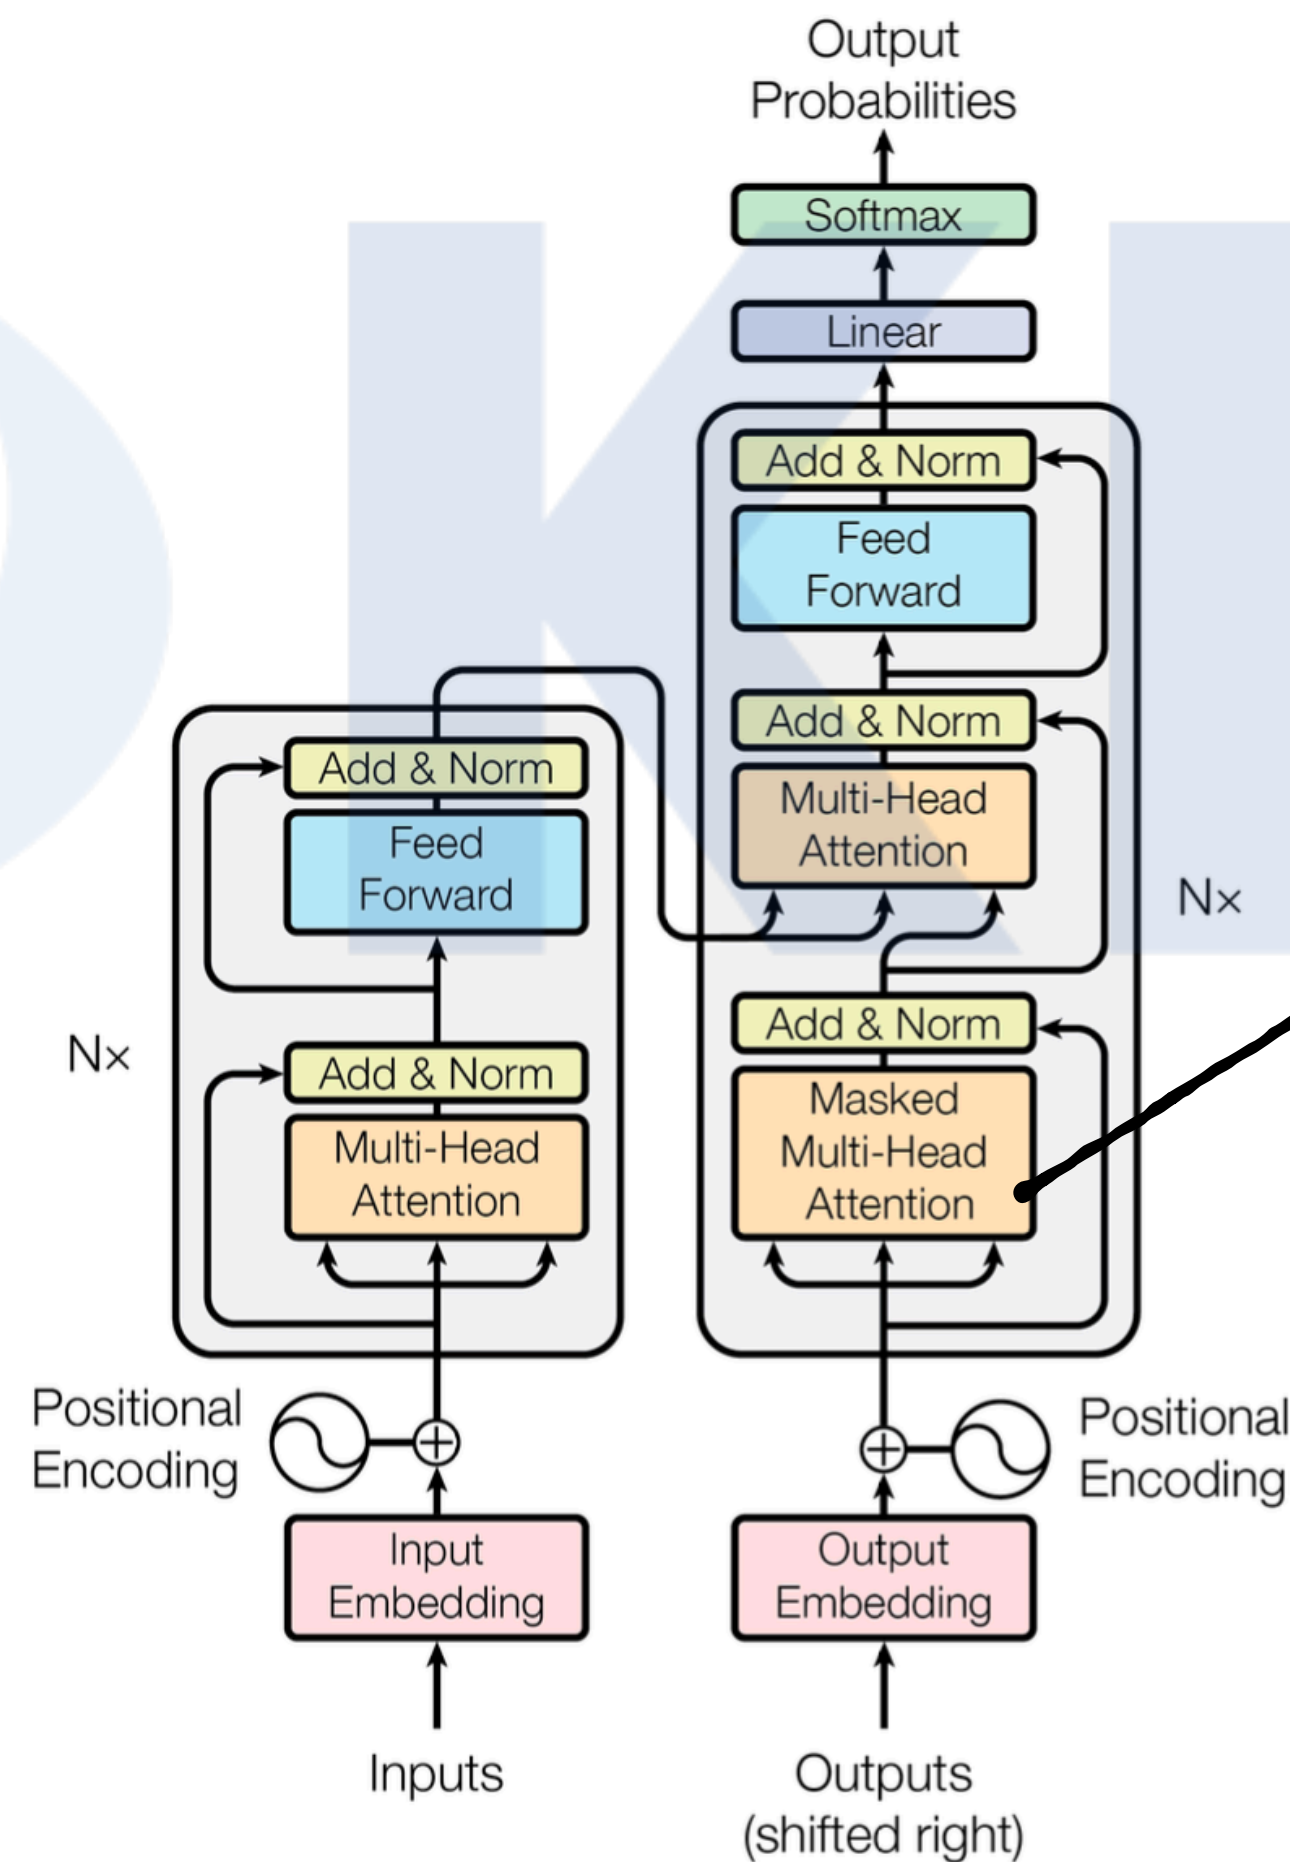

Abstract

The dominant sequence transduction models are based on complex recurrent or convolutional neural networks in an encoder and decoder configuration. The best performing such models also connect the encoder and decoder through an attention mechanism. We propose a novel, simple network architecture based solely on an attention mechanism, dispensing with recurrence and convolutions entirely. Experiments on two machine translation tasks show these models to be superior in quality while being more

Transformer model is first introduced in "attention is all you need" for language modeling. At this moment, more than 100,000 citation

Inputs are Query, Key and Value

Self Attention

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

Self Attention:

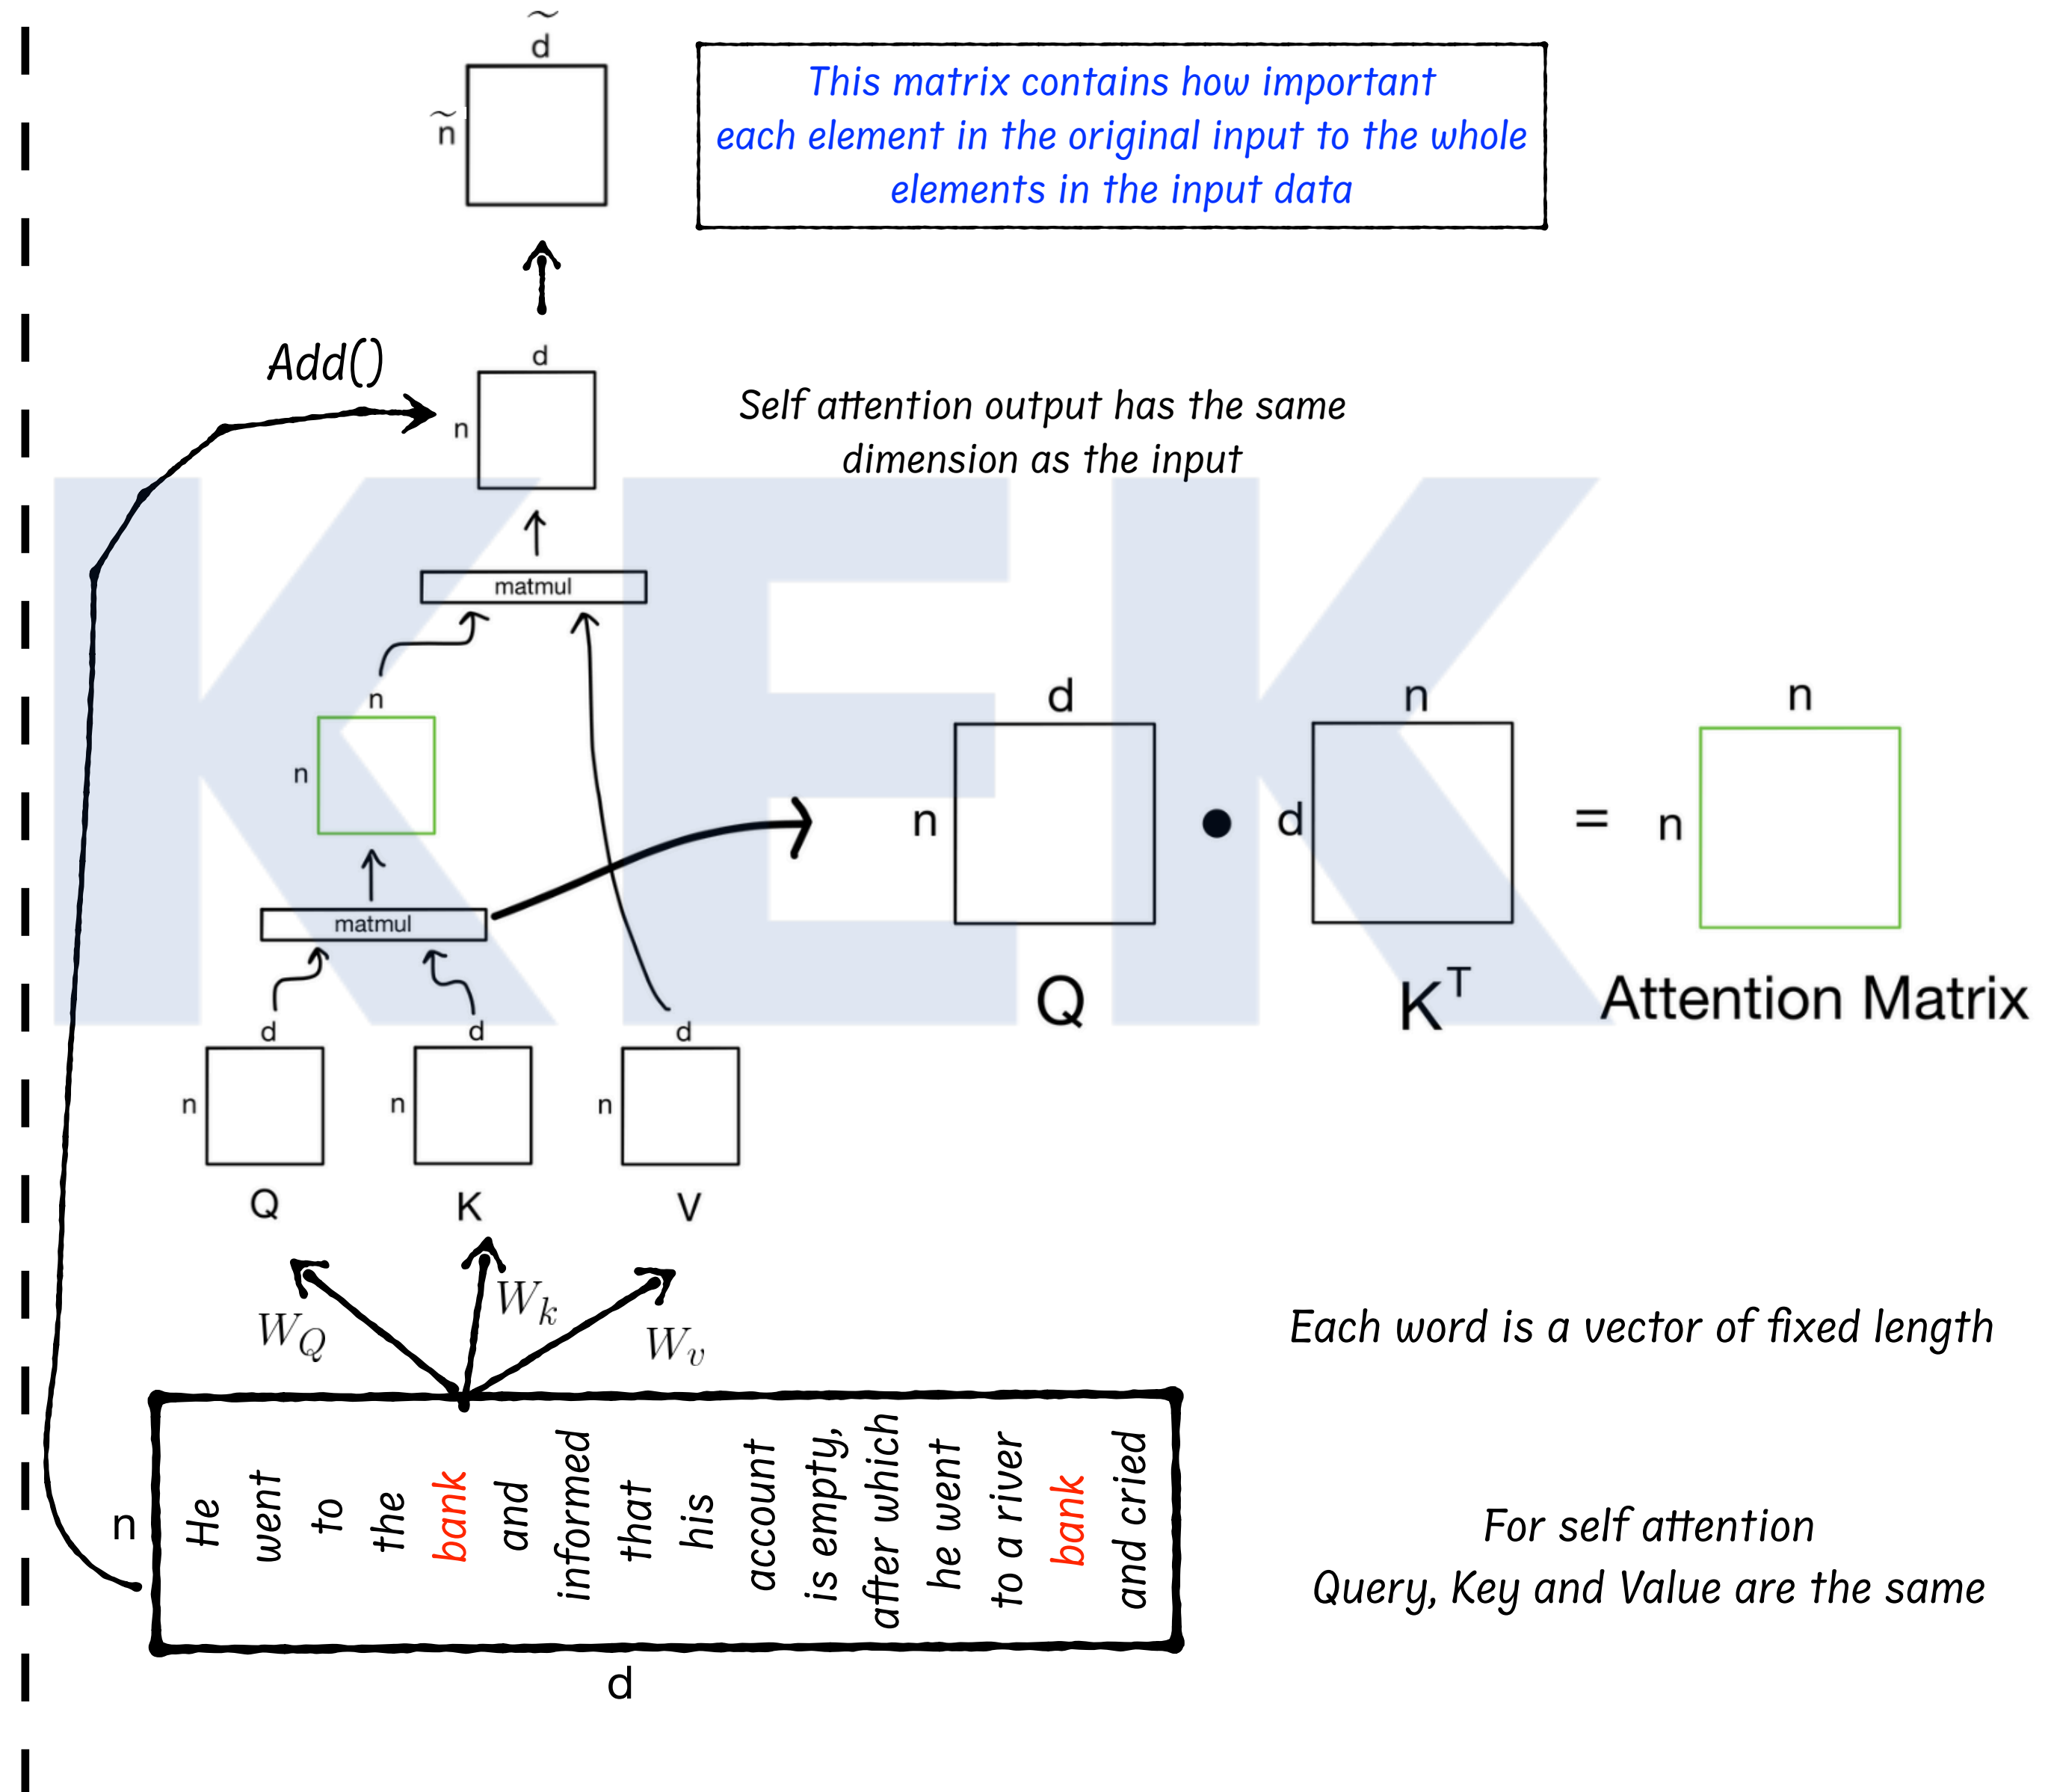

self-attention allows each element in the sequence to attend to all other elements, capturing both local and global dependencies. This is achieved through the calculation of attention scores, which are used to linearly combine the values associated with different positions.

Arxiv:2010.11929

Input Attention

It assigning different weights to different elements in the input sequence, emphasizing the more relevant parts **while discarding the less relevant ones**

Transformer for particle physics

○ Cross Attention:

1- Assign the weight matrices

$$Q^{i \times j} = X^{i \times j} \cdot W_Q^{j \times j}, \quad K^{n \times j} = S^{n \times m} \cdot W_K^{m \times j}, \quad V^{n \times j} = S^{n \times m} \cdot W_V^{m \times j}$$

For two input data sets $X^{i \times j}, S^{n \times m}$

2- Attention output

$$Z^{i \times j} = \text{softmax} \left(\frac{Q^{i \times j} \cdot (K^{n \times j})^T}{\sqrt{d}} \right) \cdot V^{n \times j}$$

Input and output have the same dimensions

3- Concatenate all heads

$$O^{i \times j} = \text{concat} \left(Z_1^{i \times j}, Z_2^{i \times j}, \dots, Z_n^{i \times j} \right) W^{(n \times j \times j)}$$

Normalizing matrix to preserve the dimension

4- Skip connection

$$\tilde{X}^{i \times j} = X^{i \times j} + O^{i \times j}$$

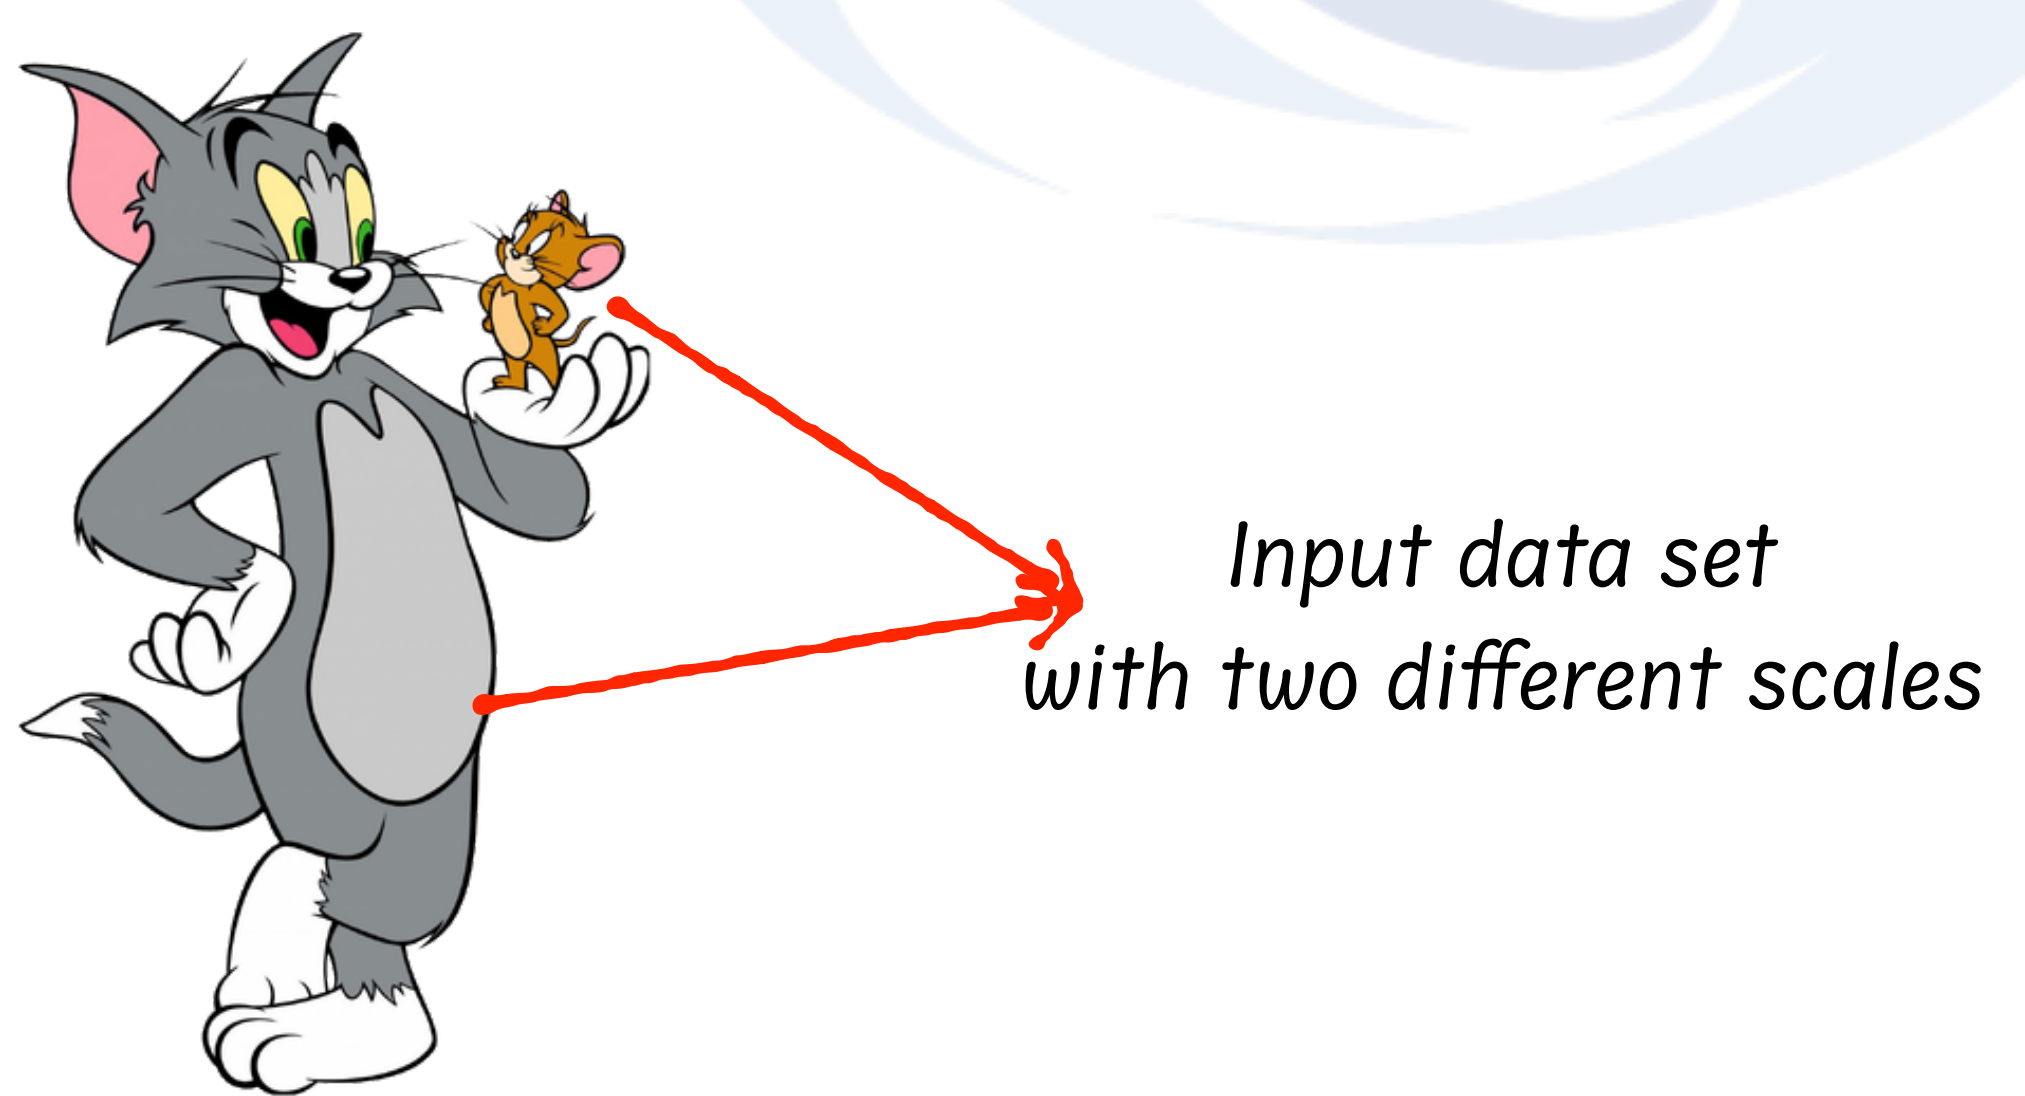

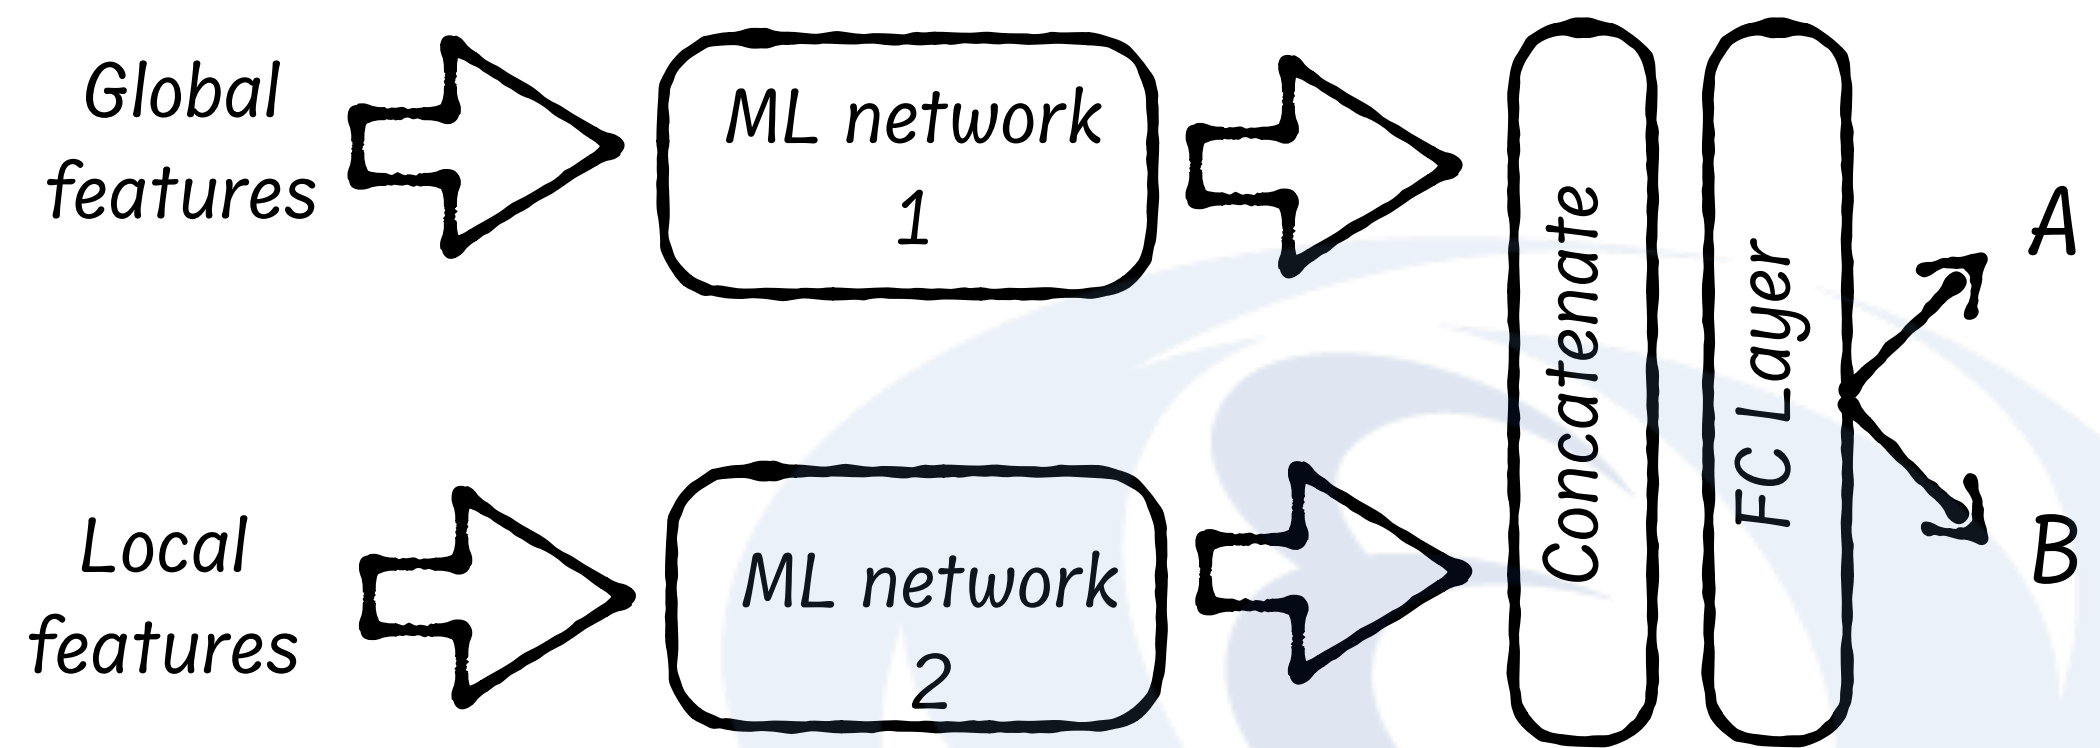

Output has the same dimension of the Input X

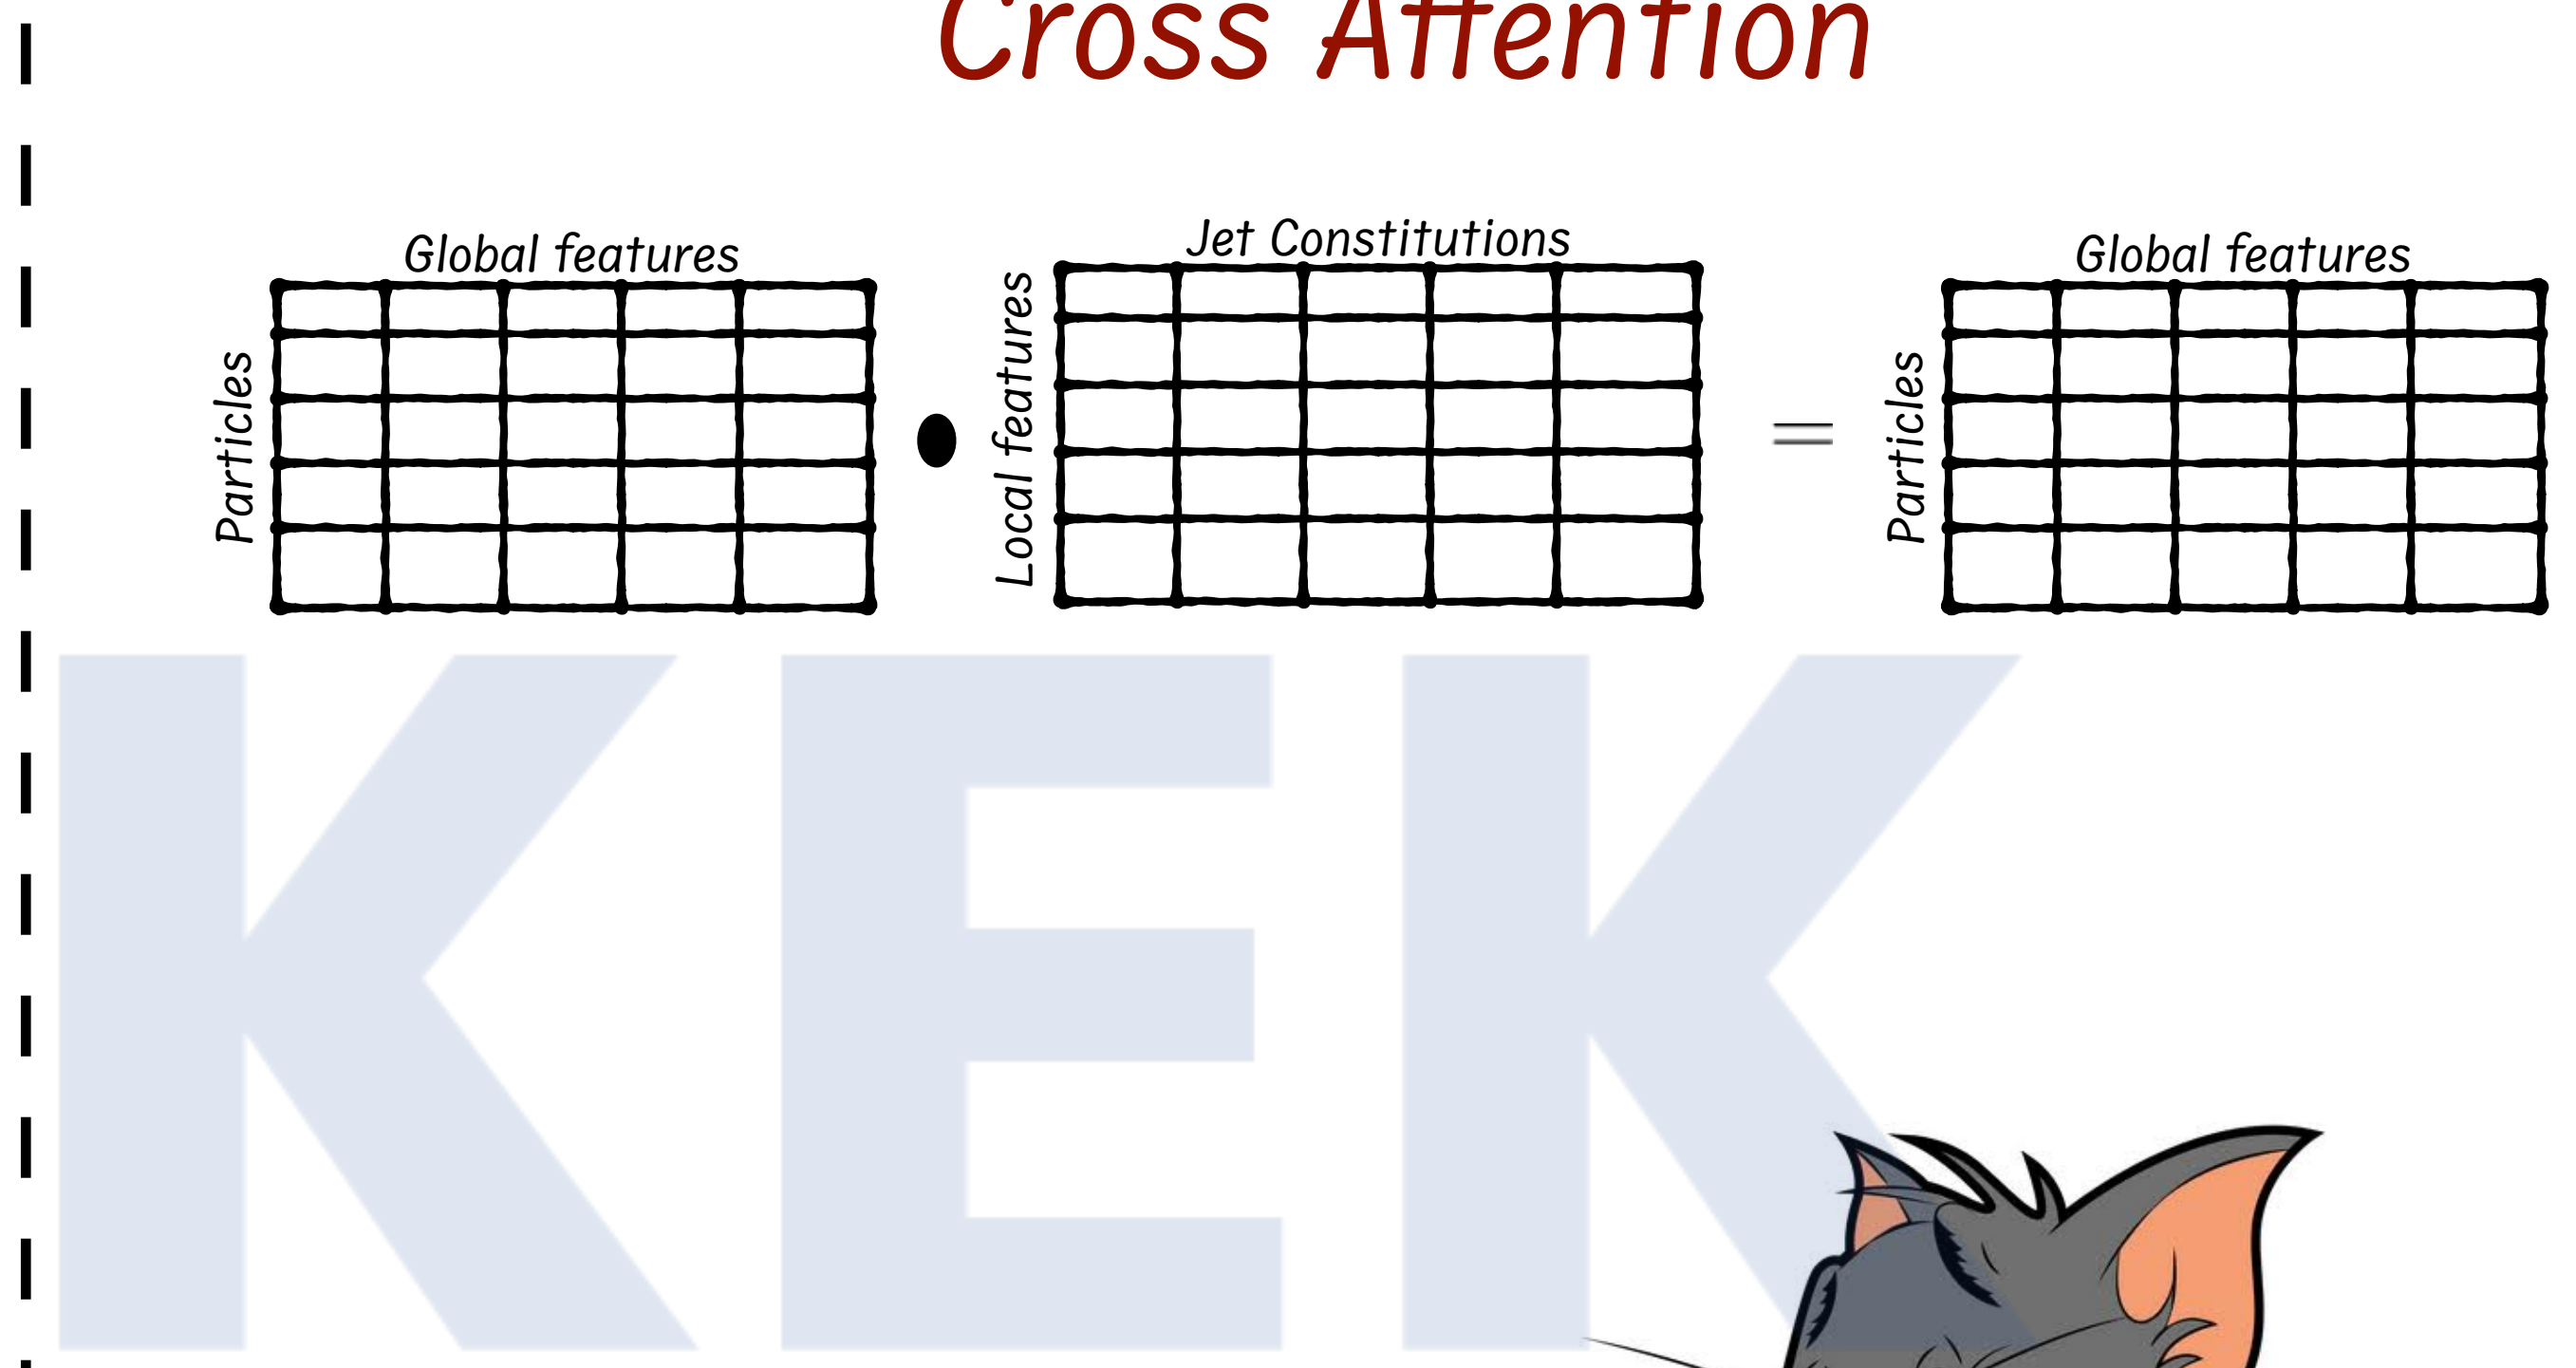

One output that encodes the important information extracted from the global and local information Of the event

Transformer for particle physics

Simple concatenation

Cross Attention

Input data set combines two data sets with one scale

Physics Example

arXiv:2401.00452
JHEP 03 (2024) 144

Data Pre-processing:

- **Centering:**

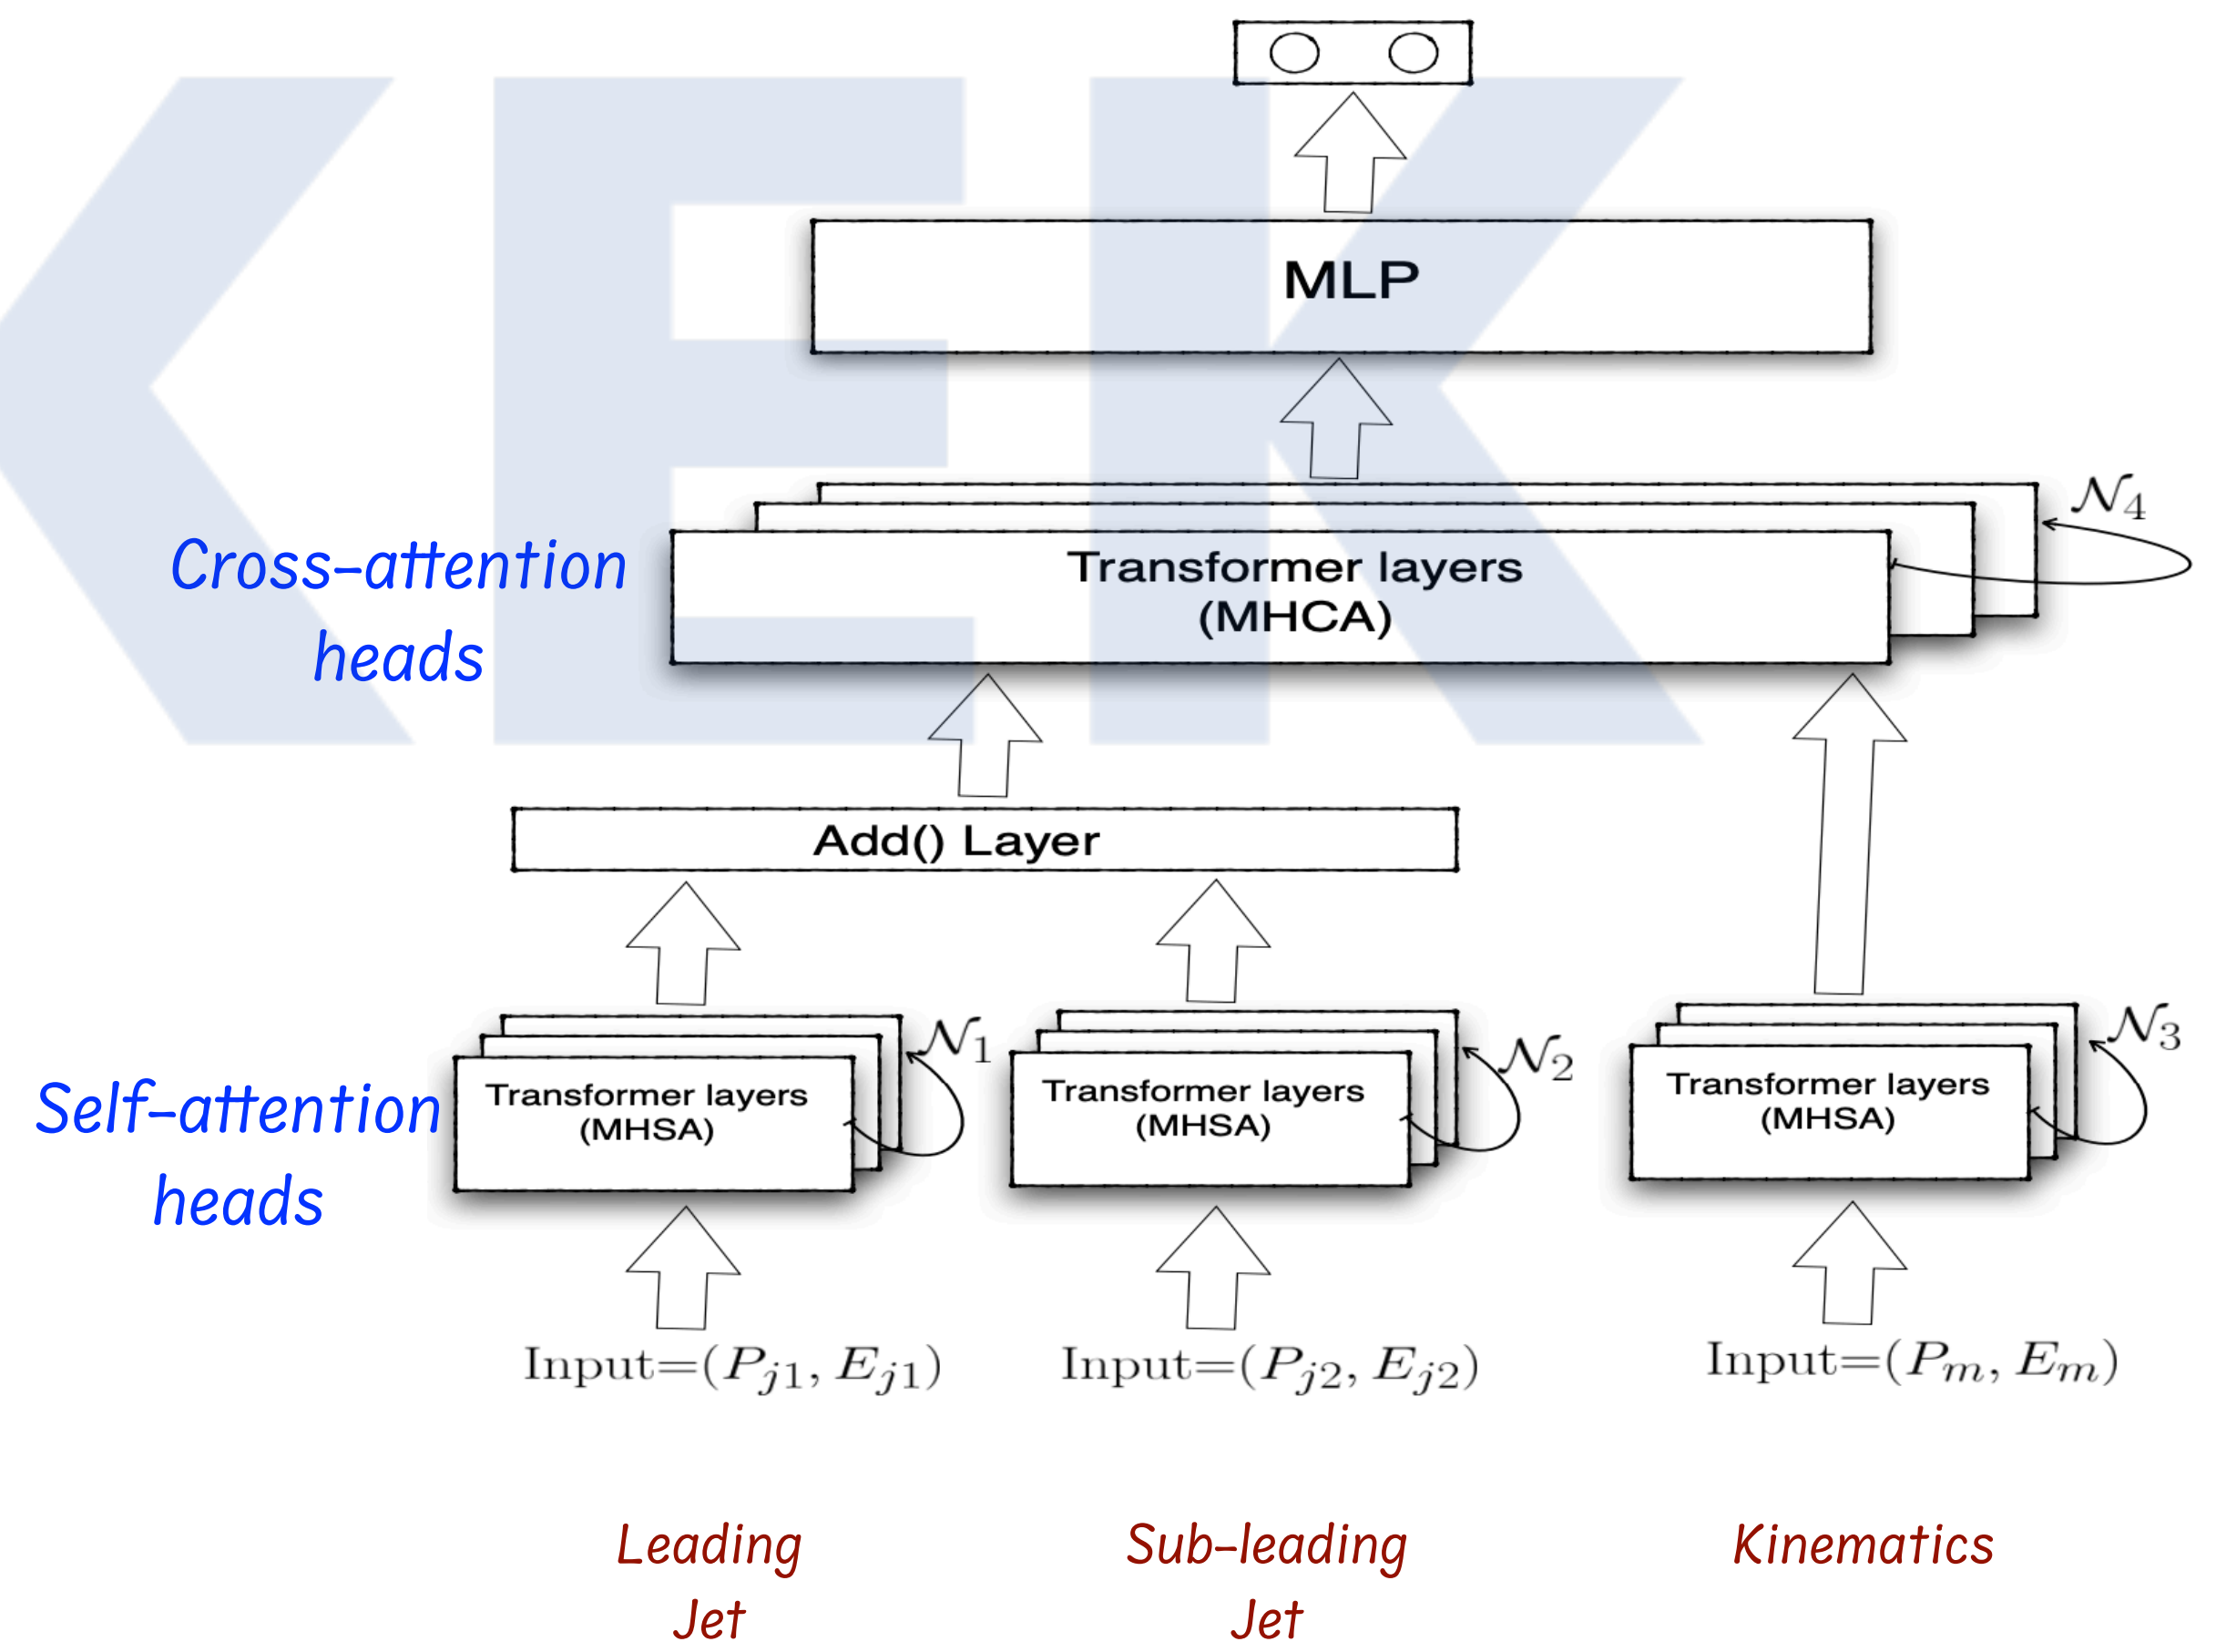

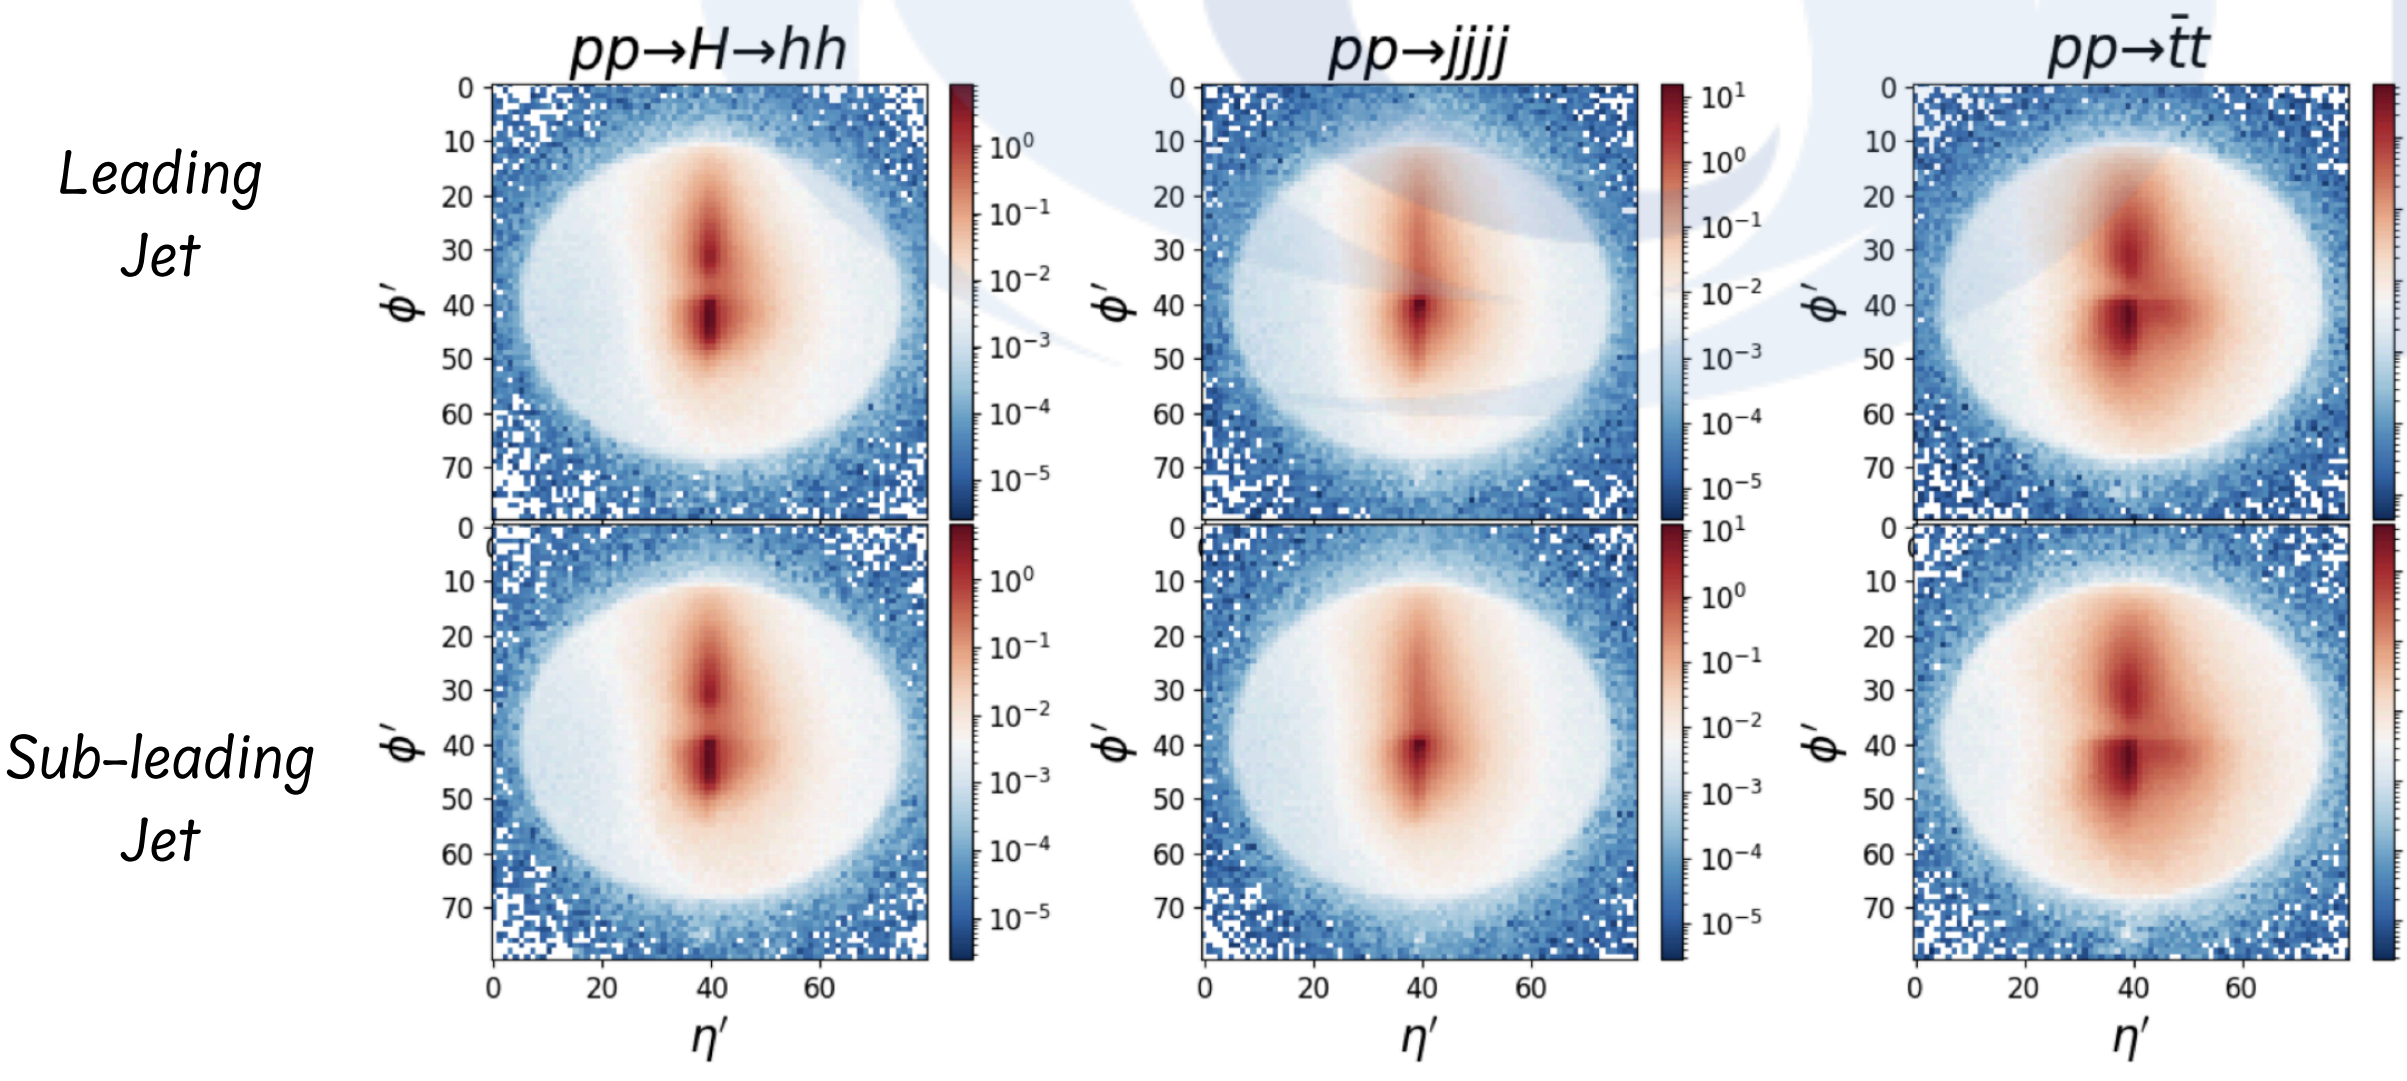

Jet contents are shifted such that the jet axis is in the center

- **Rotation:**

Rotate the jet contents in the eta-phi plane such that the jet axis is vertical

- **Flipping:**

Jet contents are reflected over the vertical axis such that the right side contains the hard radiations

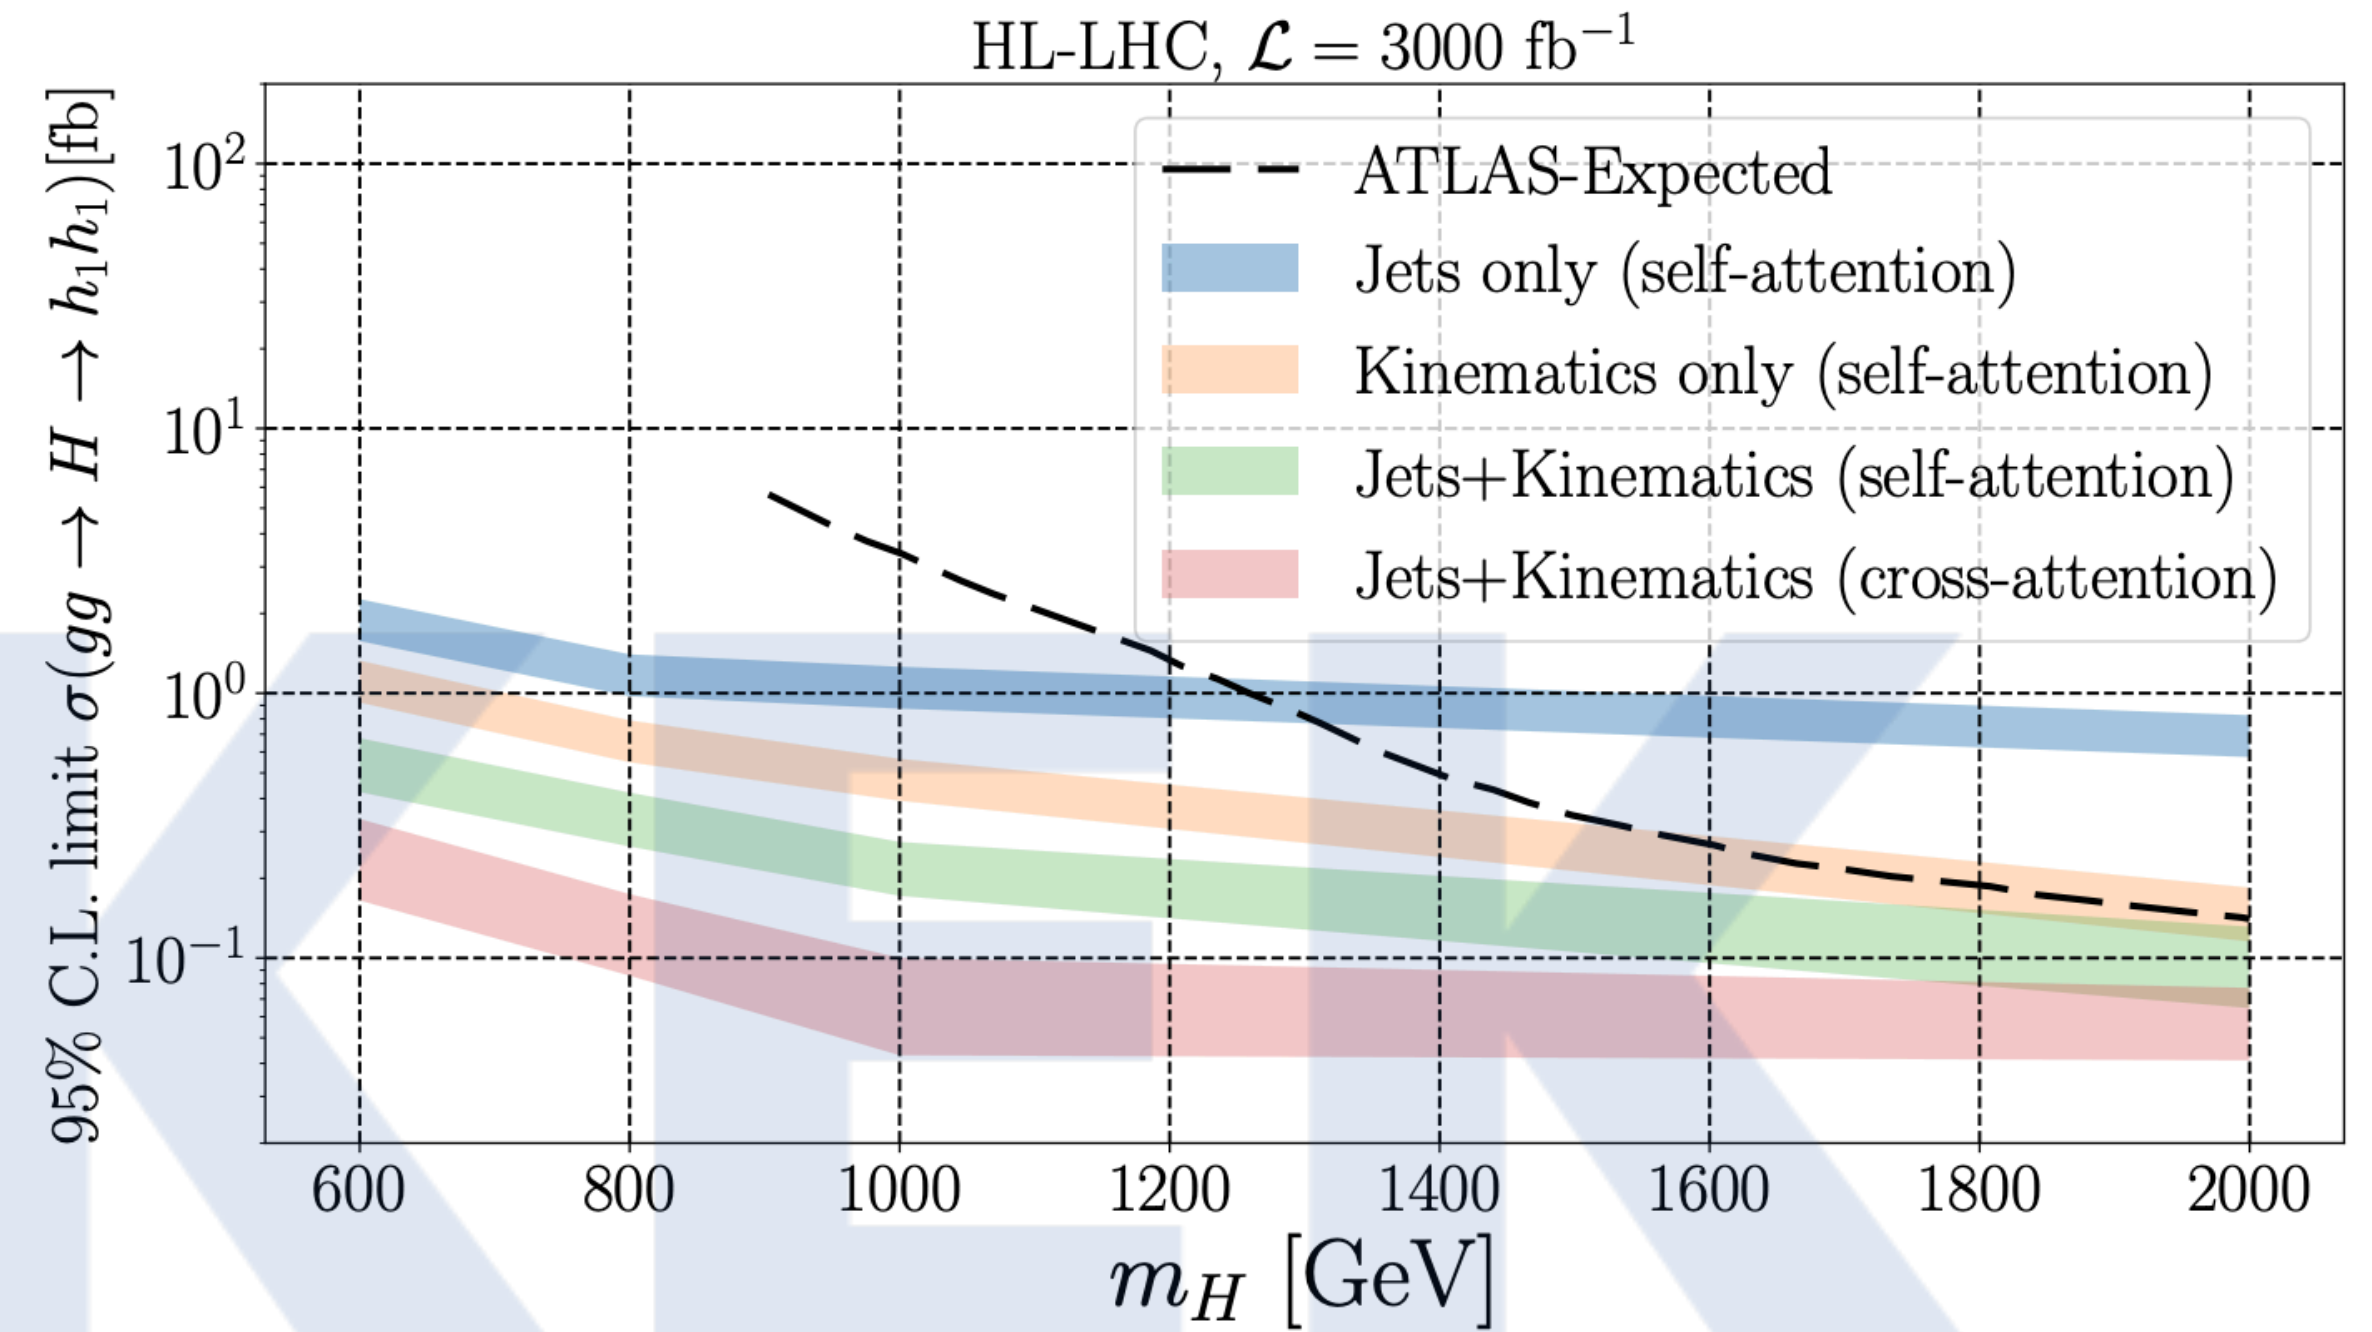

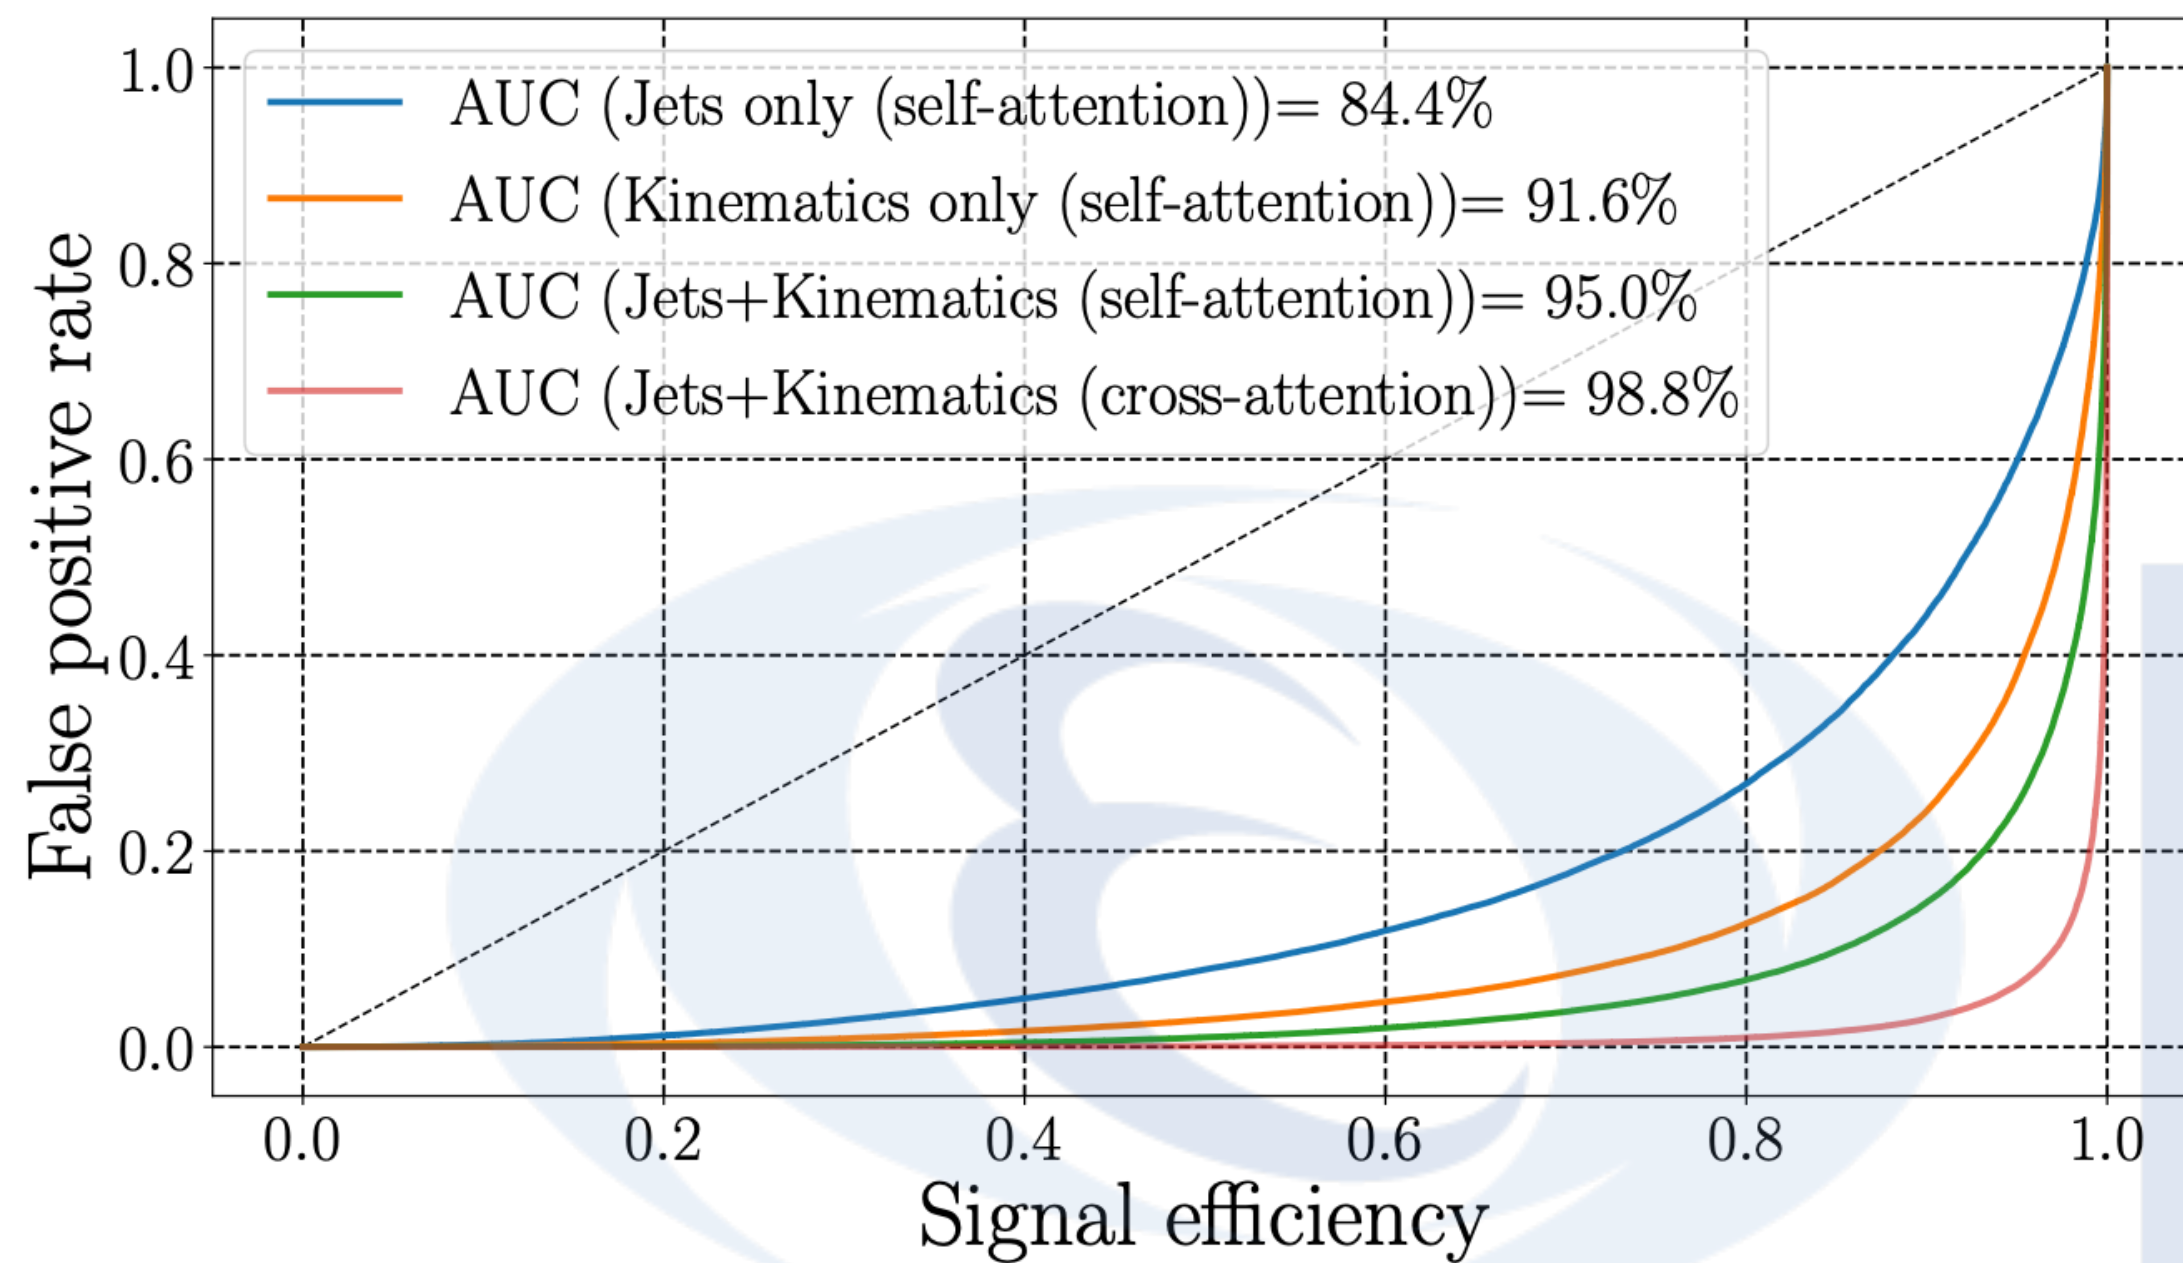

Background consists of 90% of QCD and 10% of ttbar

Results

ATLAS results are taken from Arxiv:2202.07288
and linearly scaled to 3000 1/fb integrated luminosity

ROCs for signal point with $m_H = 1$ TeV

Four models are considered:

- Transformer encoder with self attention trained on jets information only
- Transformer encoder with self attention trained on kinematics only
- Transformer encoder with self attention trained on jets information + kinematics
- Transformer encoder with cross attention trained on jets information + kinematics

For high mass range, the kinematics of the signal dominates with no much improvement of the machine learning over the basic cuts. For lower mass our network is 10 times better than ATLAS analysis.

The bands due to repeating the experiment 5 times with different train and test splitting.

Well, good results! What is next ?

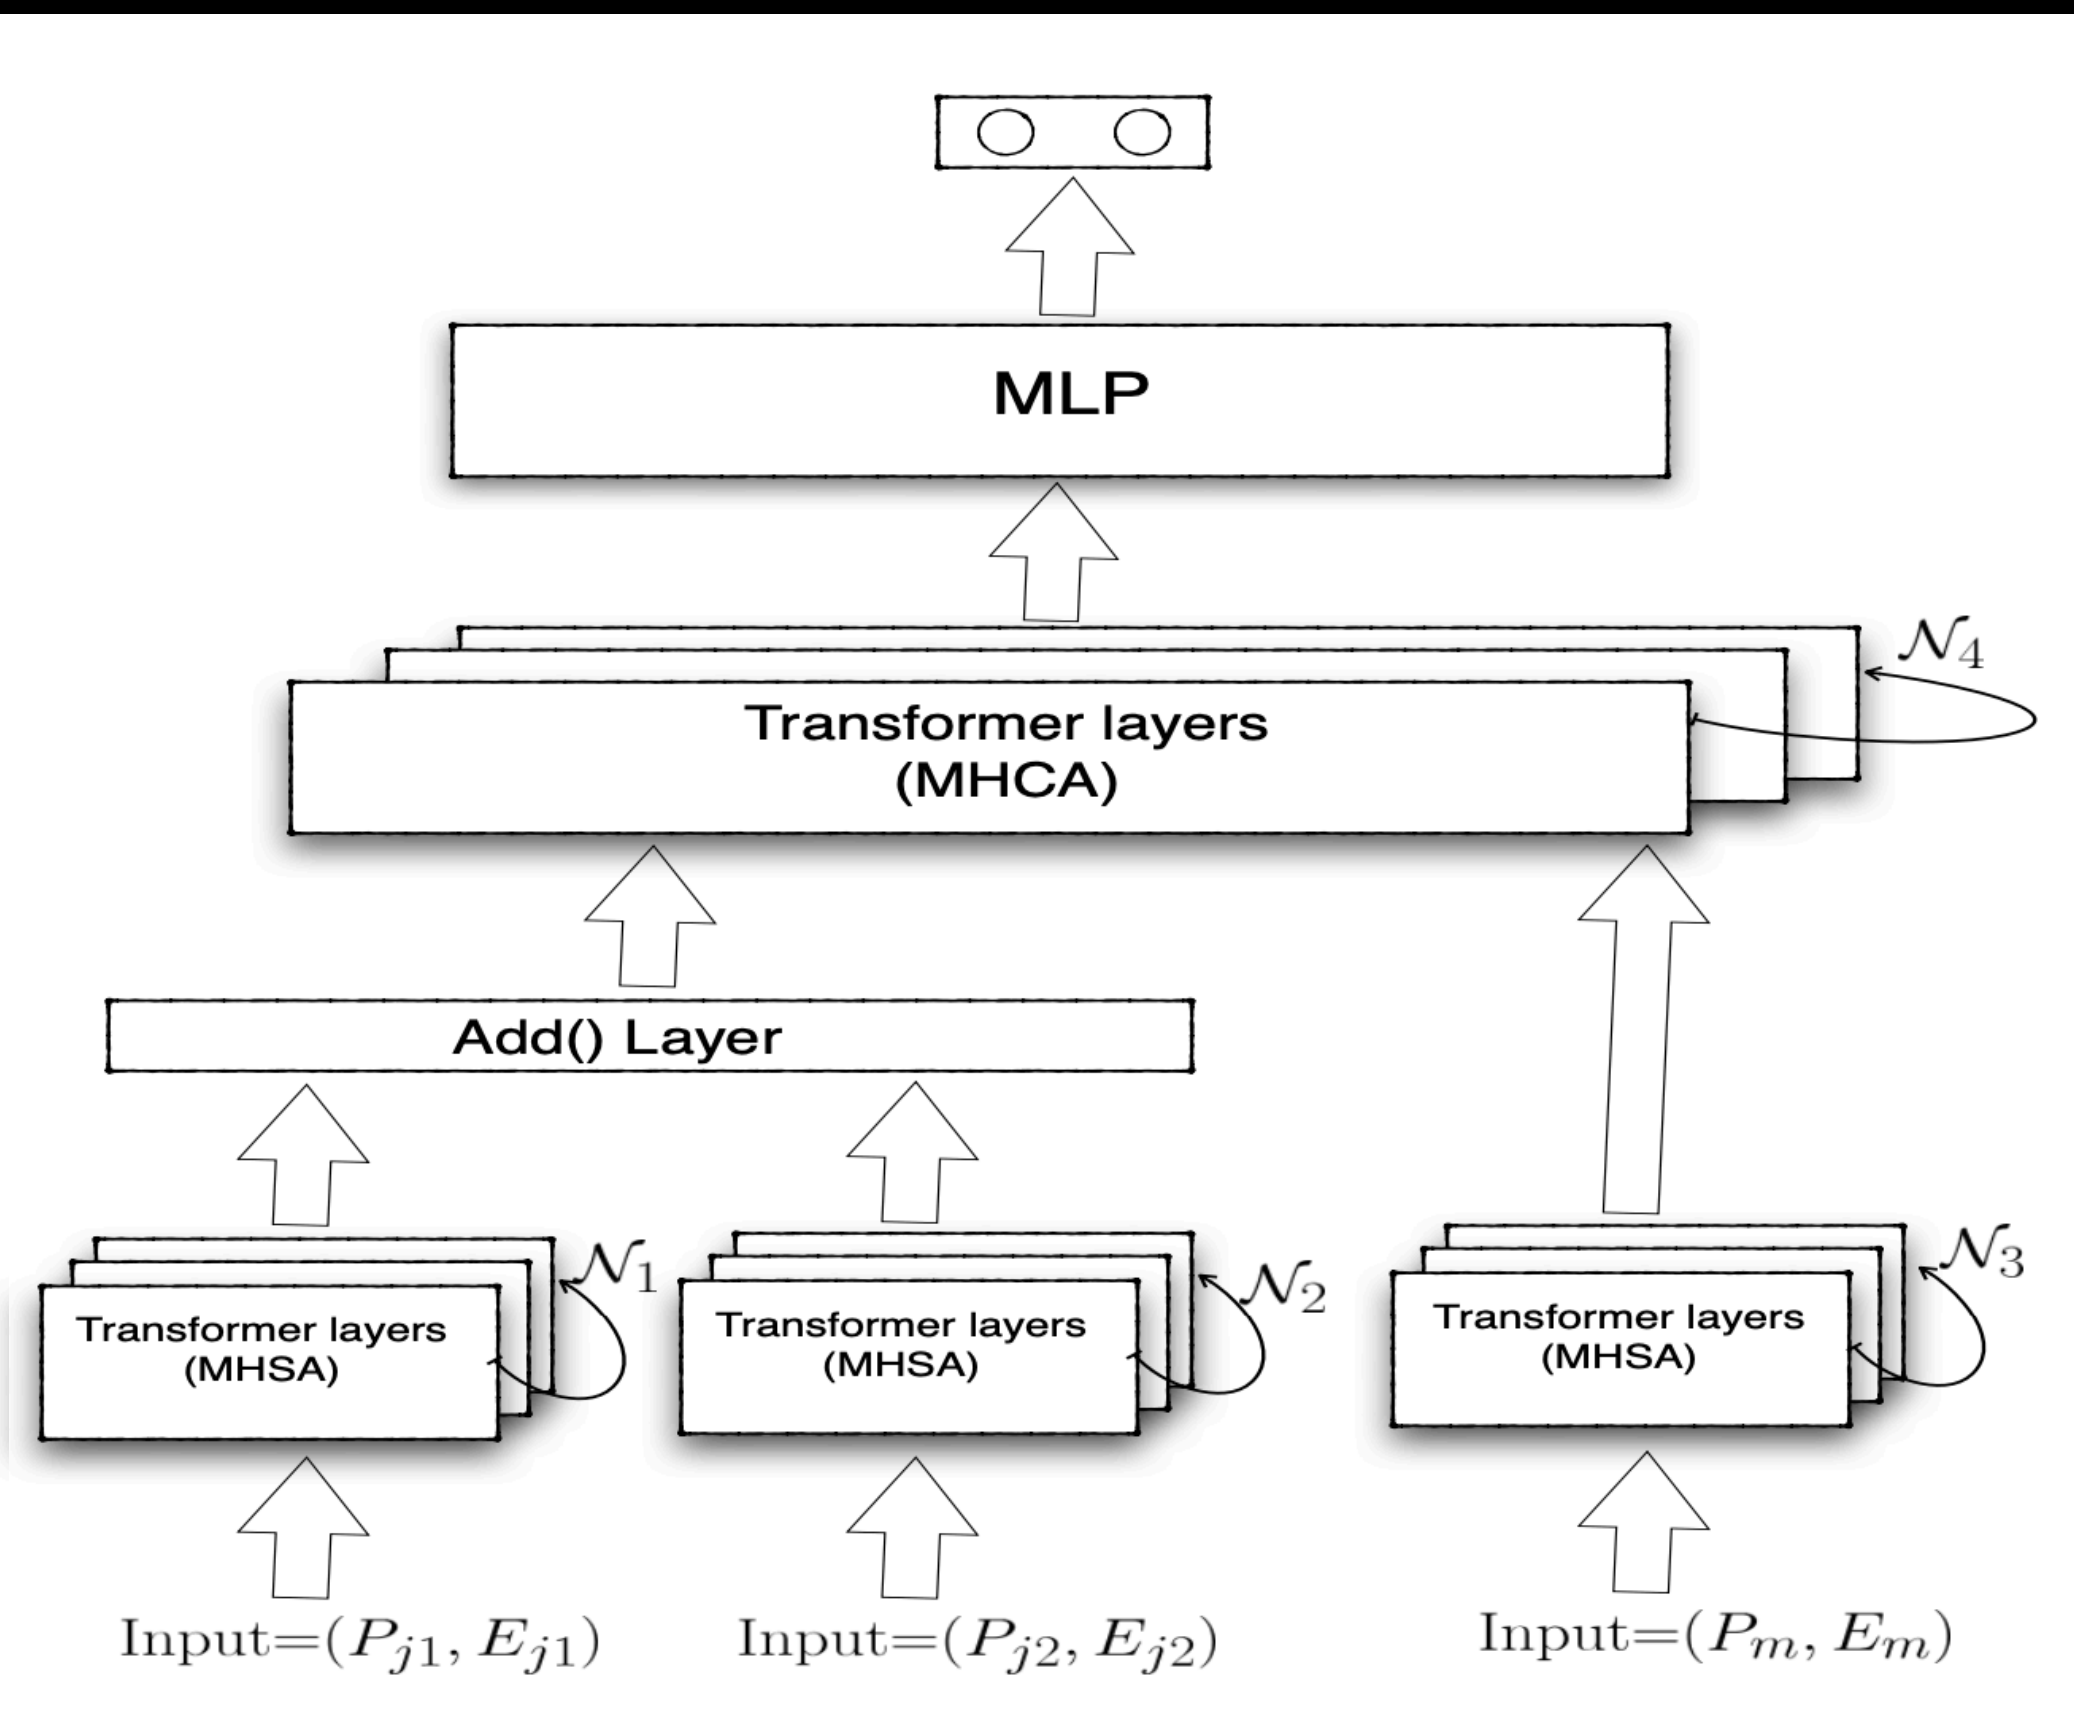

But why do we need interpretation methods?

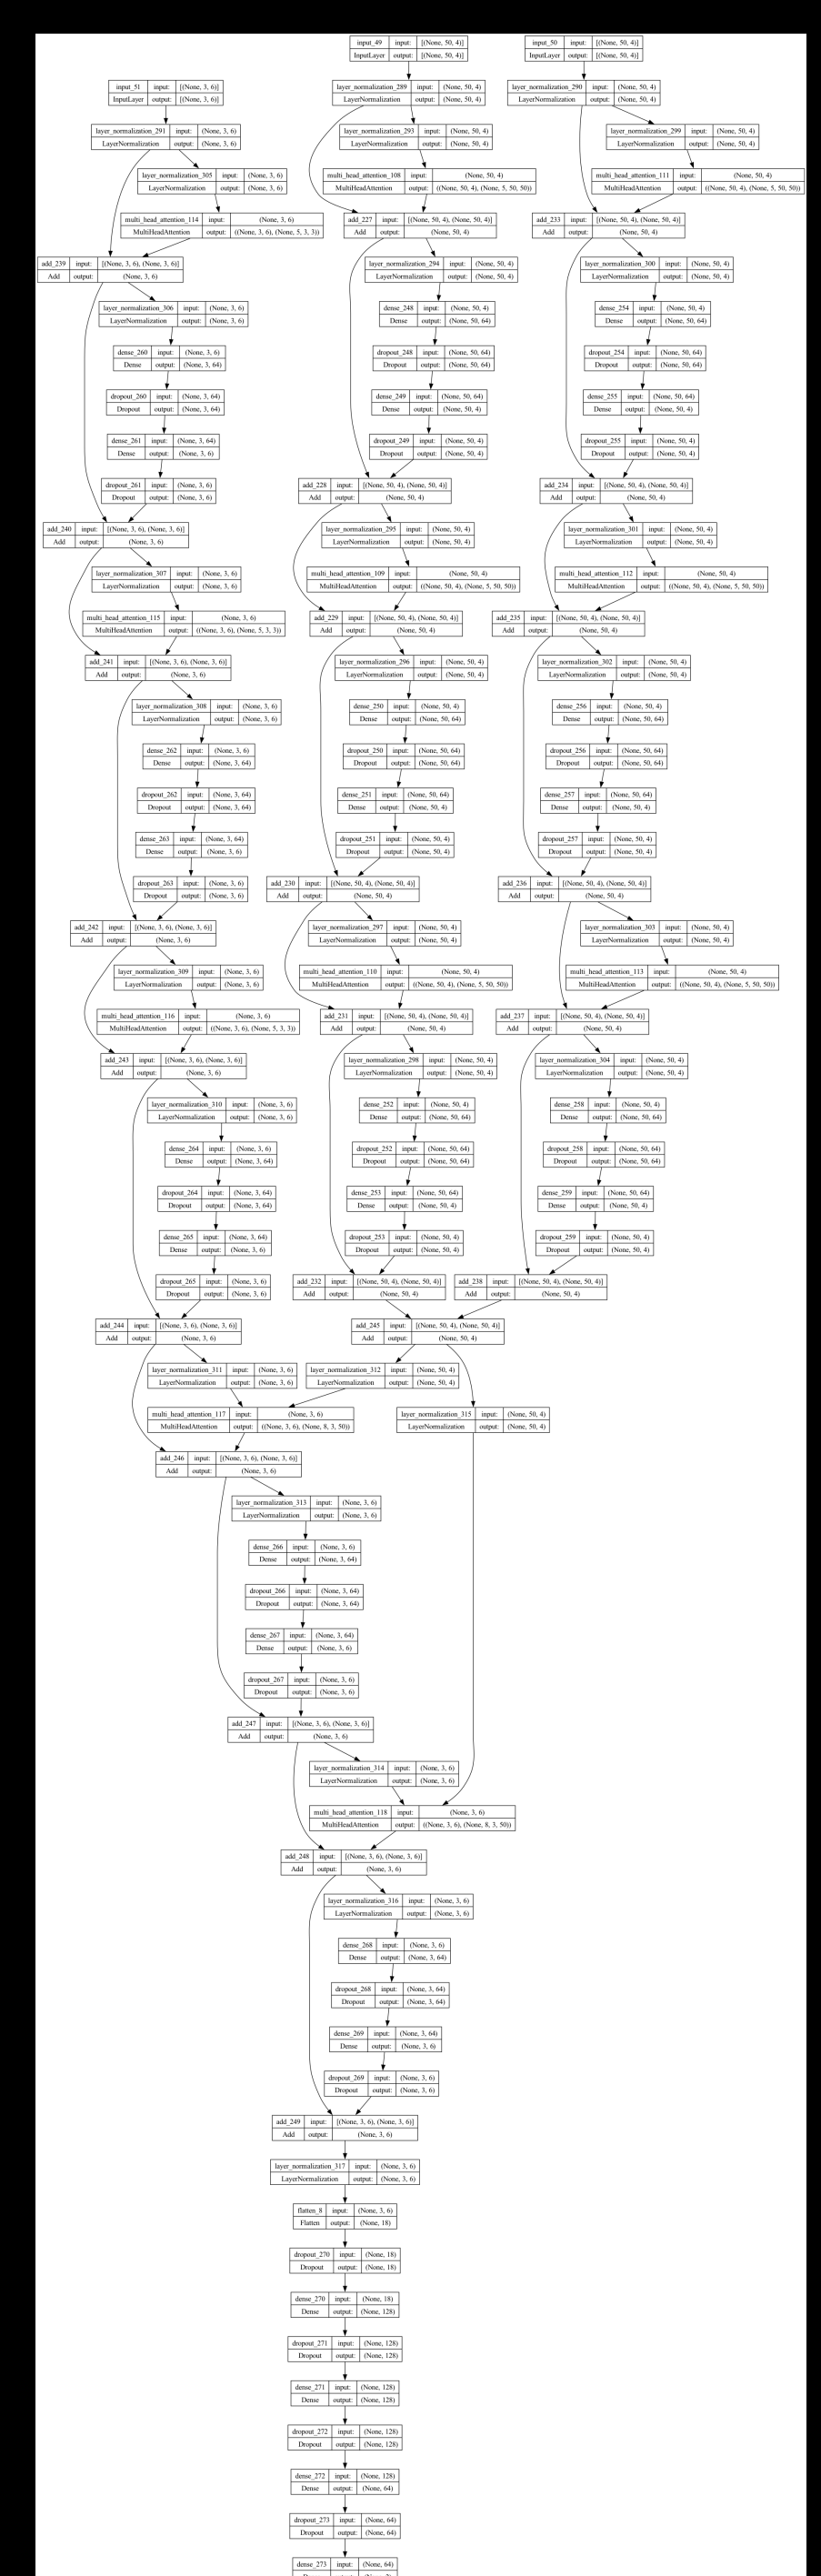

Interpretability

How the model actually looks like

What we present

It is dangerous to deal with this complex structure as a black box

Attention Maps

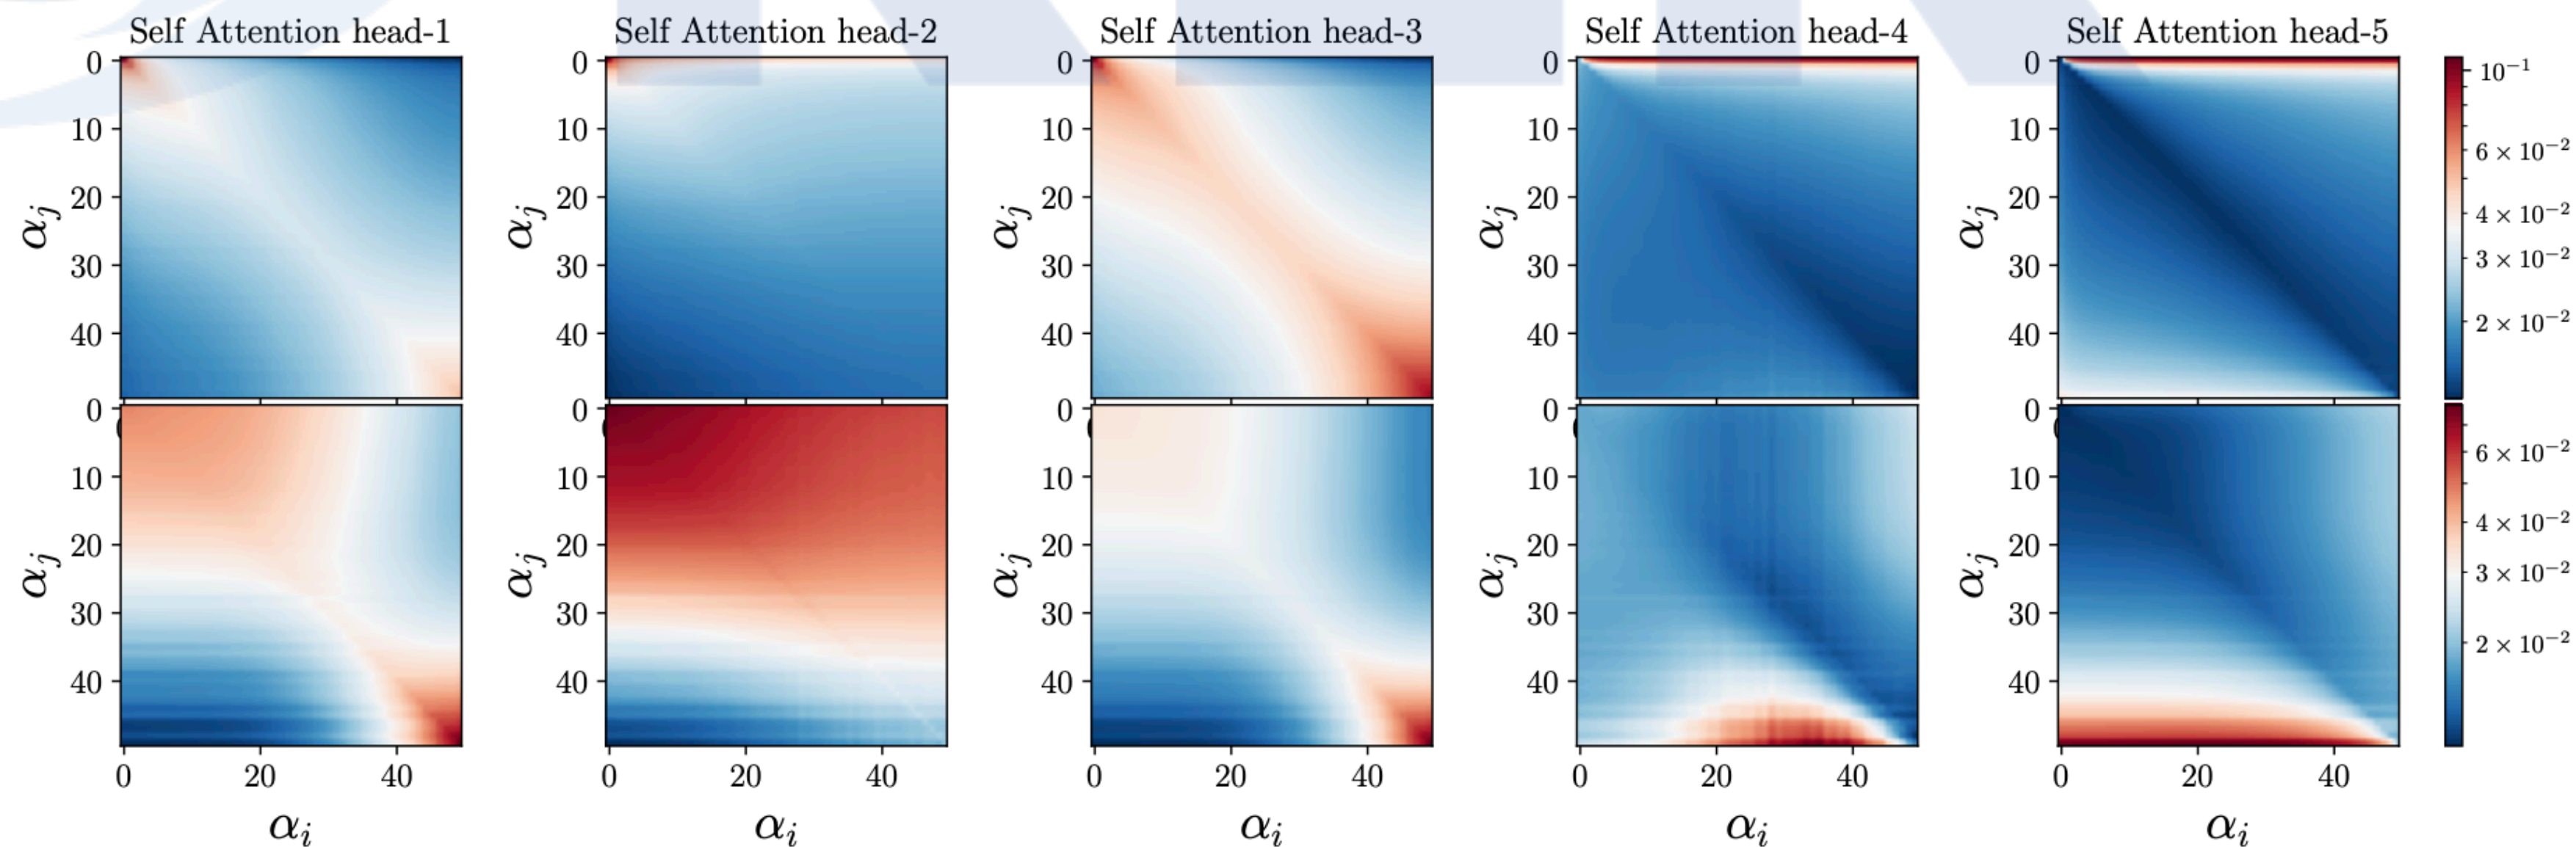

The analysis of the attention maps highlight the particle tokens that receive higher attention scores, indicating their significance in the model's decision. Also, it reveals how particle tokens relate to each other. It highlights the information extracted from the jet constituents that are relevant to the reconstructed objects.

○ **Self Attention:**

We use 5 self-attention heads for the first transformer encoder. Particles are sorted according to their p_t , with zero pixel indicates the highest momentum particle.

Attention maps of test 120K samples.
Signal heads (top) background (bottom)

The attention map values reveal that the model concentrates on the leading and second-leading jet constituents to identify events as signal-like

On the other hand, the network assign high attention to wide momentum range of the jet constituents when identify the input as background event.

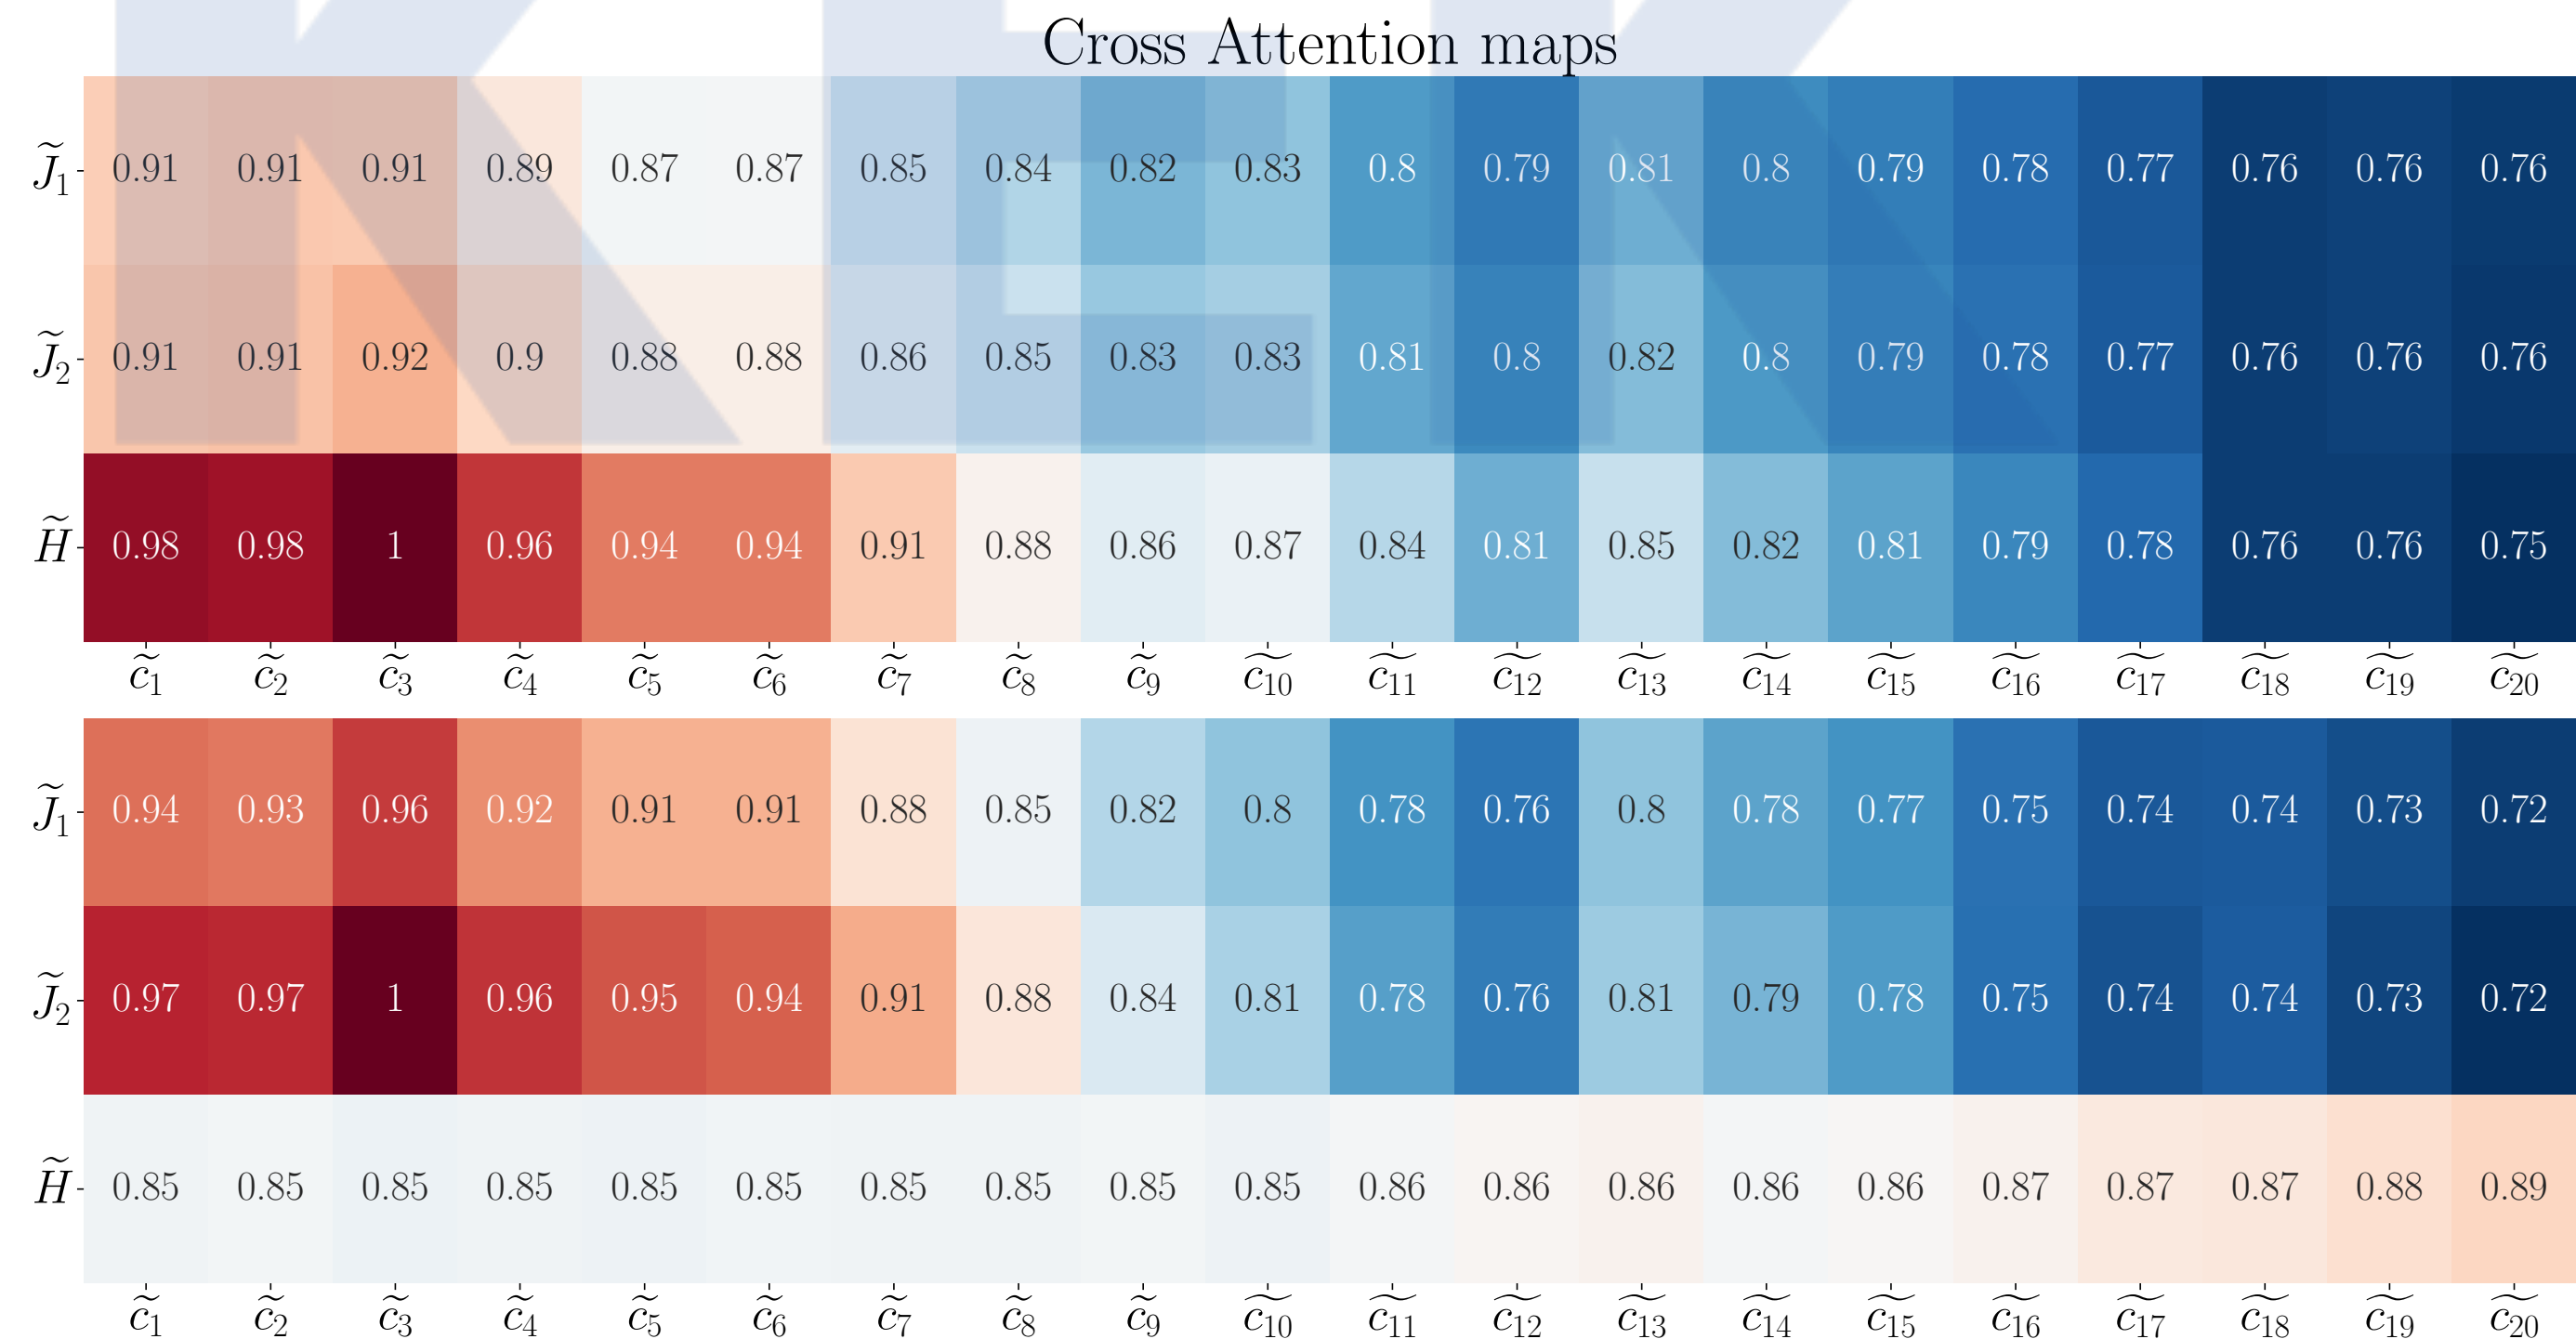

Attention Maps

○ Cross Attention:

Attention maps of test 120K samples.
Signal heads (top) background (bottom)

Average over the 8 cross attention heads.
X-axis shows the leading 20 jet constituents.
Y-axis shows the reconstructed objects

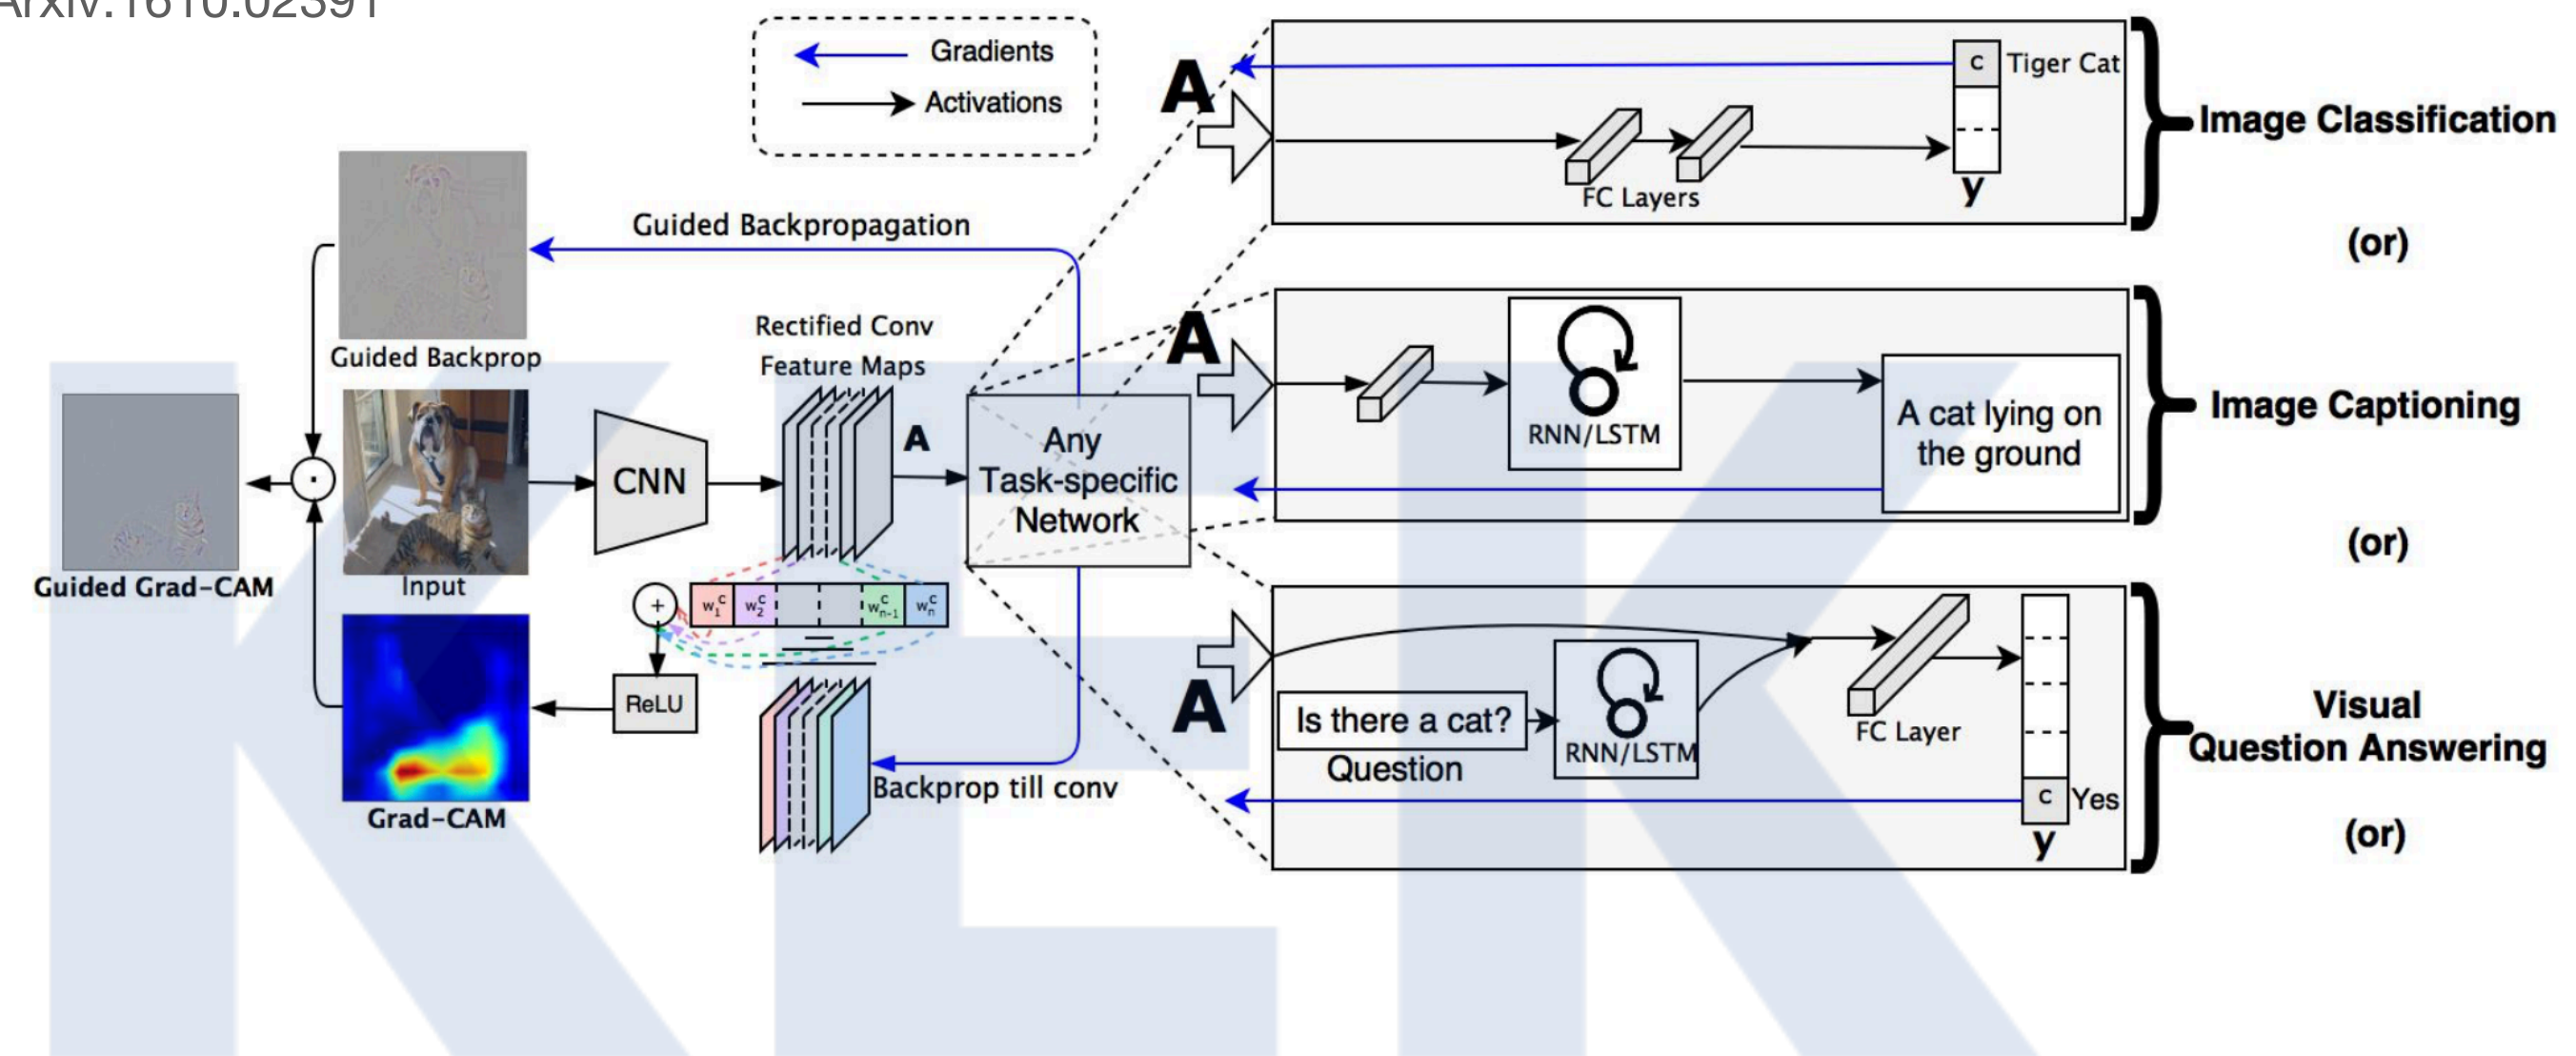

The leading constituents of the signal jets show
High attention score to the reconstructed
heavy Higgs. While background jets constituents
exhibits flat attention to the heavy Higgs

Grad-Cam

Gradient weighted Class Activation Mapping (Grad-Cam) has been first introduced in CNN model to visualize the most important pixels the model consider for his predictions.

Grad-Cam works as the following:

Arxiv:1610.02391

Arxiv:1610.02391

(a) Original Image

(c) Grad-CAM 'Cat'

(i) Grad-CAM 'Dog'

- After training split the model from the last convolution layer.
- Compute the output of the last convolution layer (A)
- Compute the gradient of the class score of the second half of the model
- Compute the average of the gradients with respect to the spatial coordinates

$$\alpha_k = \frac{1}{Z} \sum_i \sum_j \frac{\partial y}{\partial A_{ij}}$$

- Compute the weighted sum of the feature maps output (A)

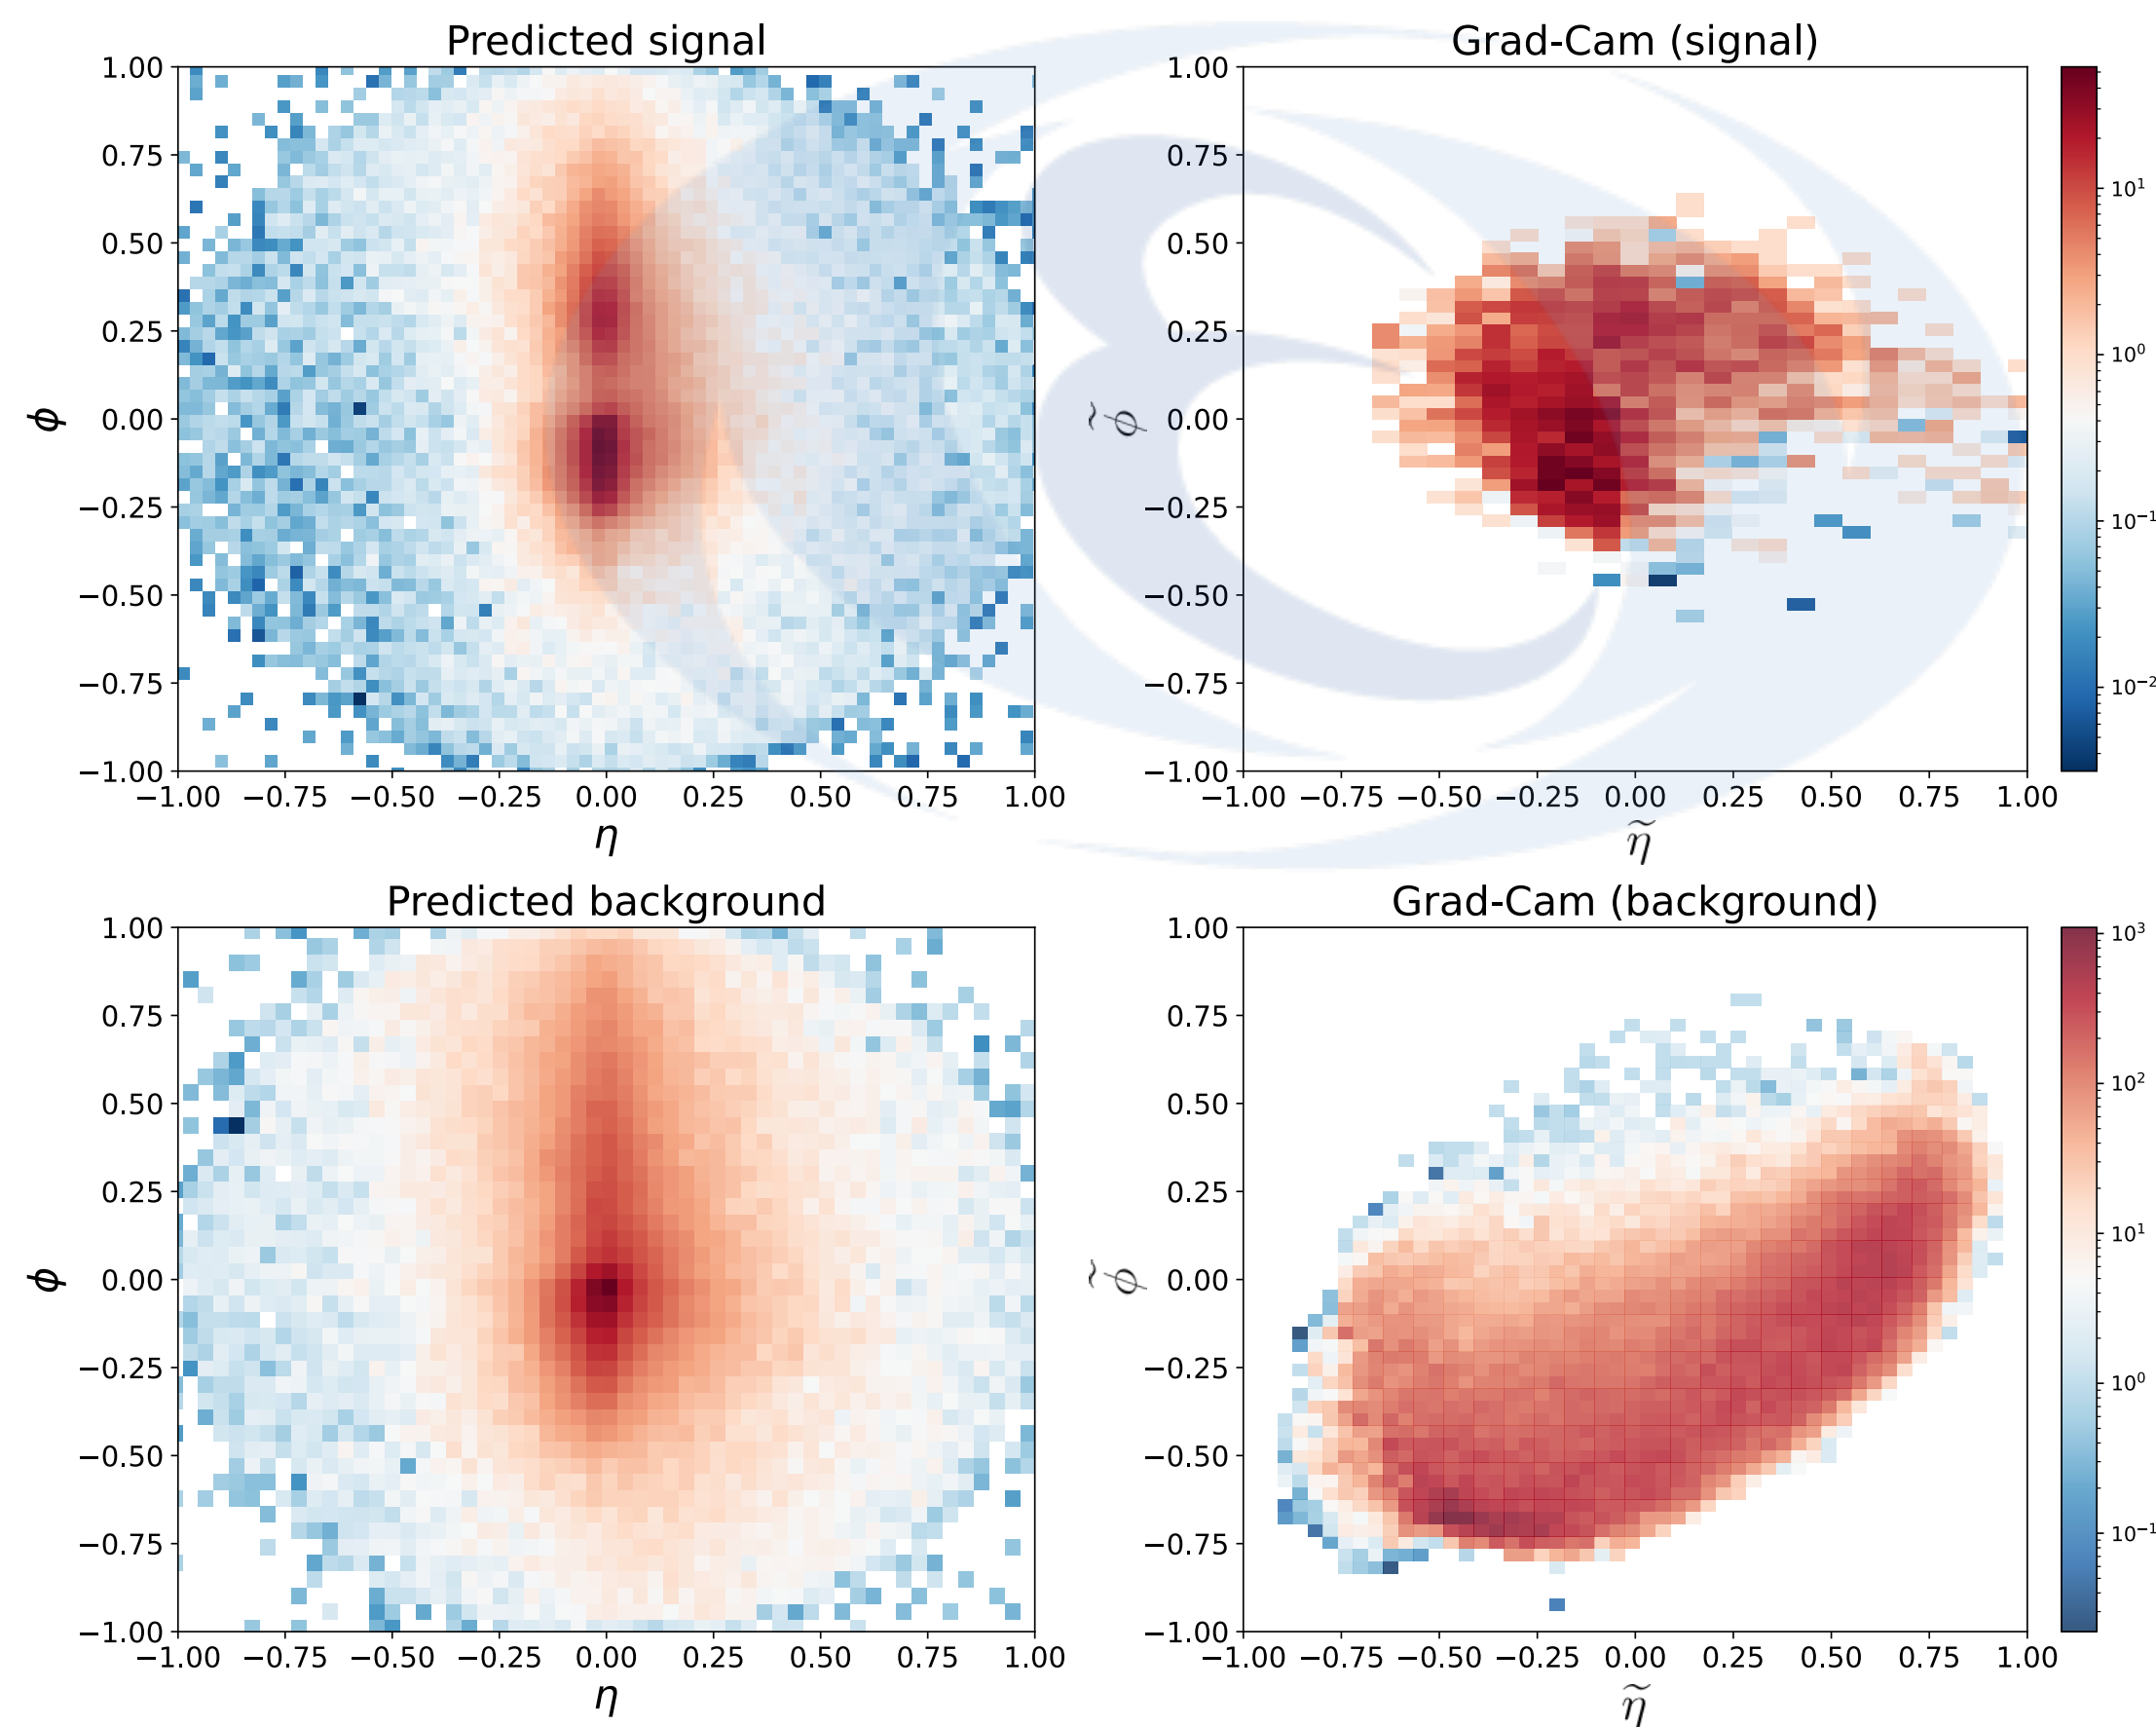

$$\text{Grad-Cam} = \text{ReLU} \left(\sum_k \alpha_k A^k \right)$$

- The resulting heatmap indicates the spatial region in which the model focuses for predictions

Grad-Cam

To visualize the region in the features space the model consider to Classify the inputs as signal or background like, we use Grad-Cam

Results for 5000 test images of the last self attention layer of the Jet transformer layer.

Grad-Cam shows that the network focuses on the two prong structure to predict the input as signal like, while it focuses on the radiation pattern of to predict the input as background like

The asymmetric pattern due to the flipping transformation
In which all hard radiation are in the positive eta range

Our code

Our code is made for public with *no hard coding*

<https://github.com/AHamamd150/Multi-Scale-Transformer-encoder>

Only one txt file to control the network structure

KEEK

Run the code via the terminal command:

```
python3 run.py input.py
```

```
sig_dir = 'sig/'
bkg_dir = 'bkg/'
outdir = 'out/'
num_classes=2
batch_size= 500
epoch = 15
mlp_units = [128, 64]
masked = False
#####Loss functions and optimizer#####
