

SIS tests in UCAP for TCDIL and TDIS, bunch length interlocks & SIS V2

J. Wenninger

Interlocks on TCDILs (and TDIS revision)

- Since Run1 we are discussing a **redundant interlock on TCDI collimators** to avoid mishaps as happened many years ago when the SPS optics was changed (Q20 vs Q26).
 - Gaps were left at Q26 settings while SPS ran with Q20.
- The idea was to **re-use the beta* gap interlock concept** of the ring collimators. **TL optics ID telegrams** were added (same role as beta*), the optics ID is filled by LHC SIS.
 - Optics ID checked after every SPS pulse using the TL quadrupole currents.
- **Nothing ever happened...**
- **Resurrection** of the idea (not at Easter) in software form, use as test for **SIS interlocks in UCAP**.
- Implement an **Injection** interlock in **SIS**.

Interlocks on TCDILs (and TDIS revision) (2)

- **Test of gap versus SIS reference in LSA**, optionally also **check of optics ID** validity.
 - The reference is in a BP attached to the hypercycle → can accommodate different settings for pp and ions.
- This concept happens to also **fit the needs for the TDIS** → use the opportunity to make TDIS gap interlock in SIS more flexible (no more fixed limit in project xml configuration).

The screenshot shows the 'Settings Management' application with the following components:

- Source:** A list of beam processes, with 'LHC-SIS-REF-INJ-6.8TeV-ATS-2m-2024' selected.
- Parameter Group:** A list of parameters, with 'LHC SIS-REF' selected.
- Property:** A list of properties, with 'SisInjCollimatorGap/GapInterlock' selected.
- Device/Property:** A list of device/property pairs, including 'SisGap.TCDIV.88121/GapInterlock'.
- Setting Part:** Radio buttons for 'Value', 'Target', and 'Correction', with 'Value' selected.
- Time Base:** A dropdown menu set to 'LHC-SIS-REF-INJ-6.8TeV-ATS-2m-2024'.
- Table:** A table with columns 'PARAMETER' and 'Value'. The table contains three rows:

PARAMETER	Value
SisGap.TCDIV.88121/GapInterlock#gapLowerLimit	11.9
SisGap.TCDIV.88121/GapInterlock#gapUpperLimit	12.7
SisGap.TCDIV.88121/GapInterlock#opticsId	7233

If opticsID = 0 → not checked
(for TDIS)

Interlocks on TCDILs (and TDIS revision) (3)

- UCAP transformation (1 per TCDIL and 3 per TDIS [A,B,C]) on node **UCAP-NODE-LHC-SIS**.
- Each transformation publishes:
 - All input values (measured gaps, gap interlock limits, optics IDs),
 - **Boolean result → used in SIS for test.**
 - Text message explaining interlock test decision.
- Once stable → can be **logged in nxcals** (not yet).
- During the **2023 ion run**:
 - All **TCDIL tests** were **active during part of the run** – all ok.
 - For the TDIS, the **new tests** based on UCAP **ran in parallel to the old versions** – ok.
- In **2024**:
 - **TCDIL tests** will become **operational**.
 - **New TDIS tests** will **replace old versions**.

And more UCAP

- The SIS tests on the **injection buckets** (based on BQMs, prevents over-injection is more than 1 bunch in a ring & checks bucket requests vs AGK limit) and **SPS beam intensity interlocks** (total I, intermediate I, etc) – both acting on **injection** – were converted to UCAP to evaluate the conversion time.
 - It is quick (< 2 hours for a test type).
- In 2024 both tests will run in UCAP transformations (node **UCAP-NODE-LHC-SIS**).
 - Same publication philosophy than for TCDIL/TDIS gap tests (all inputs, test result, text message).
 - SPS intensity threshold as setting in LSA.

```
UCAP-NODE-LHC-SIS> dl

LHCSIS-INJ.TDISC.A4R8.B2 -> CollimatorGapInterlock RUNNING (inputs: 3102805, results: 3102805, no issues)
Listed 22 devices (22 transformations, 0 actors)
```

SIS JAVA tests to UCAP?

PROs

- Smaller projects/entities can help simplify maintenance and tests.
- Detailed test data (input values, thresholds...) may be **published** → **NXCALS** for diagnostics.

CONs

- Not a single data buffer like in SIS, may imply adding data concentrator layers to avoid replication.
- **Lack of *user-friendly* diagnostics** (subscription state, transformation state, structure of nodes etc).
 - Only the OP Michi tool can help.
- **UCAP becomes mission critical.**
 - HW reliability, SW updates etc.
- **Changing names of devices, parameters, fields** is heavy and disruptive since It implies CCDE updates.
 - Must change transformation, SIS and CCDE at the same time... Testing??

Too early to engage in a “massive” conversion to UCAP !

Bunch length interlocks in SIS

- Since a few years there is an **interlock on the bunch length in SIS** to cover a failure of the longitudinal blow up in the ramp.
 - The initial motivation was driven by **collimator temperatures**.
 - The threshold was set to **0.8 ns for ≥ 500 bunches** (on 15s averages).
 - **Only active in the ramp**.
- With the problems of the vacuum modules, one should consider **tightening the threshold** to avoid issues with more vacuum modules. Failures of the longitudinal blowup are rare but do happen !

Bunch lengths in 2023 - ramp

- Bunch length along the ramp in 2023 for fills with ≥ 200 bunches (and stable beams) – shown below.
- The lower bounds are quite reproducible.
- **With respect to 0.8 ns**, there is quite some **margin**: proposal **to raise the threshold to 1.05 ns** for 2024 (for ≥ 300 bunches). To be updated based on further experience, or improved blow up etc.

Bunch lengths in 2023 – stable beams

- Bunch length in 2023 during stable beams for fills with ≥ 200 bunches.
- One can see how we progressively raised the bunch length for which the blow up is triggered.
- **Automated blow-up trigger process (UCAP) is very effective.**
- One could consider **extending the SIS interlock to stable beams**, and/or add a **BigSister warning message** when the length drops below XX ns.
 - Interlock with some protection against BQM outages (changes are very very slow).

SIS V2

- BE-CSS has allocated resources (2 staffs at xx %) to prepare a **new version of SIS, SIS V2**.
- The aim is to clean-up old technology items (JMS, Groovy), simplify the code that grew over the years, change the way tests are declared etc.
- BE-CCS is working on a **first prototype for the injectors** to be testable in **2024** in parallel to the existing system, an activity that started without FB from OP.
- This subject was discussed in an **OP technical meeting** in January (with BE-CSS) with presentations by OP and CSS.
 - It was clear that the **OP and CCS ideas and concepts were not fully aligned**.
 - OP pointed out the need for good monitoring of input data (UCAP weaknesses), for tools to regenerate large lists of identical interlocks (for ex LHC PCs), etc
- As an **outcome of the meeting**:
 - CSS agreed that **UCAP** deserves **more development**, for ex. “administration/monitoring” tools.
 - A **CSS-OP team with representatives from all machines** will work on **requirements and implementation of SIS V2**.
