

Triple Higgs couplings

ECFA WG1-SRCH

A. Kundu, A. Le Yaouanc, P. Mondal, G. Moultaka, F. Richard
Calcutta-Orsay-Montpellier collaboration

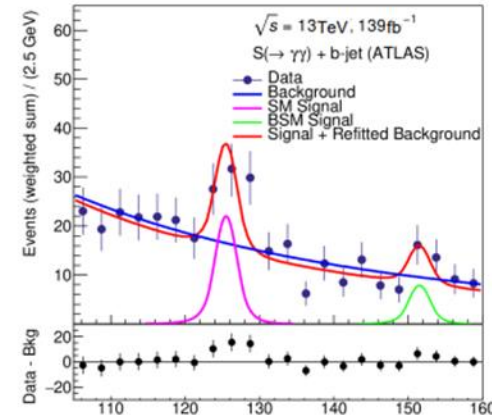

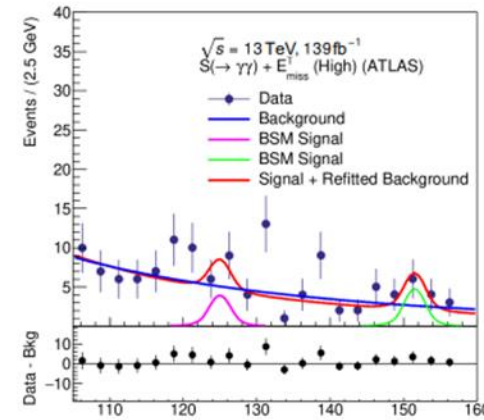

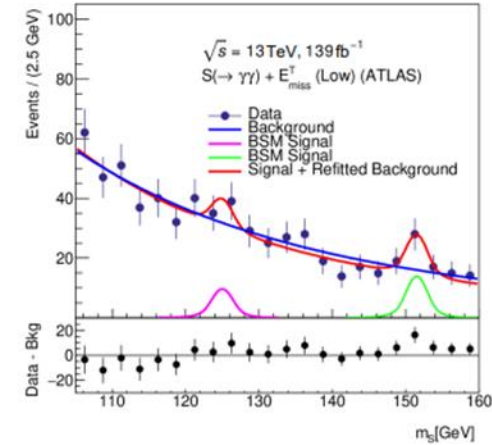

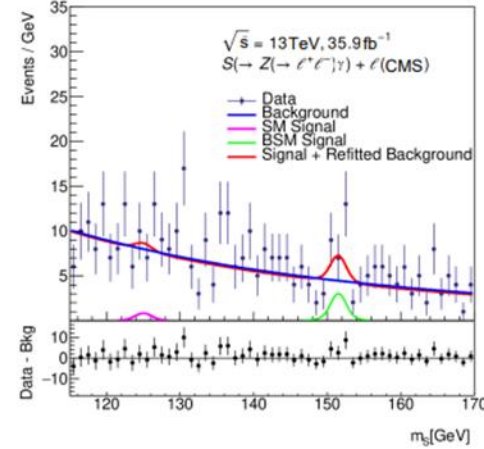

Introduction

- Measuring $h^* \rightarrow hh$ appears as a high priority of our field
- A very low SM x-section, 30 fb, with very large backgrounds makes this a formidable task
- Much easier if there are **resonances** $H \rightarrow hh$
- Direct evidence, 3.8 sd : **A(420) \rightarrow H(320) \rightarrow hh \rightarrow bbbb**
[2210.05415](#)
- BR(W+W+) \sim 10% using Haber et al. SR implies light charged Higgs $H^\pm(130)$ [2312.00420](#) and a dominant BR(H+H+)
- These results naturally fit into **Georgi Machacek** model
- This model associates to **H+(130)**, seen in [2302.11739](#) a light **CP-odd A** with similar mass

A(151)

- There is a candidate $A(151) \rightarrow \gamma\gamma$ at 4.8 s.d. when asking $+b$ or E_{miss} or leptons [2404.1492](https://arxiv.org/abs/2404.1492)
- CP odd suggested by non observation in ZZ
- GM predicts that $A(420) \rightarrow H(320) Z \rightarrow A(151) A(151) Z$
- Could easily be found using the same technique used for $h(125)h(125)$
- Gives a cross section in $b\bar{b}b\bar{b}$ 4 times larger than $h(125)h(125)$
- Should provide the most convincing ($\gg 5$ sd) BSM LH signal so far !
- **Three discoveries at a time : A(420), H(320), A (151) .**

e-GM summary

- All but one among the **10 e-GM scalars** have a candidate indicated by LHC data

GM	Isosinglet	h95	h125
	Isotriplet	A151	H+130
	Isofiveplet	H320	H+375 H++450
E-GM	Extradoublet	A420	H650 H+ ?

- Physical states differ substantially from the GM Isospin states (see below)
- There is a candidate **H⁺ → A(420)W⁺ → ttW⁺**

Example of a matrix solution

$$H_1^0 = \phi^{0,r},$$

$$H_1^{0r} = \sqrt{\frac{1}{3}}\xi^0 + \sqrt{\frac{2}{3}}\chi^{0,r}.$$

$$H_5^0 = \sqrt{\frac{2}{3}}\xi^0 - \sqrt{\frac{1}{3}}\chi^{0,r},$$

	1	2	3	4	htt/SM	ZZ/SM	WW/SM
	$\phi 1$	$\phi 2$	χ	ξ			
H95	0.08	-0.56	0	0.82	- 0.96	- 0.34	0.59
H125	0.58	0.58	0.47	0.33	0.99	0.99	1.1
H320	0.31	0.30	-0.88	0.17	0.52	- 1.29	- 0.38
H650	0.74	-0.52	0	-0.43	- 0.90	- 0.43	- 0.91

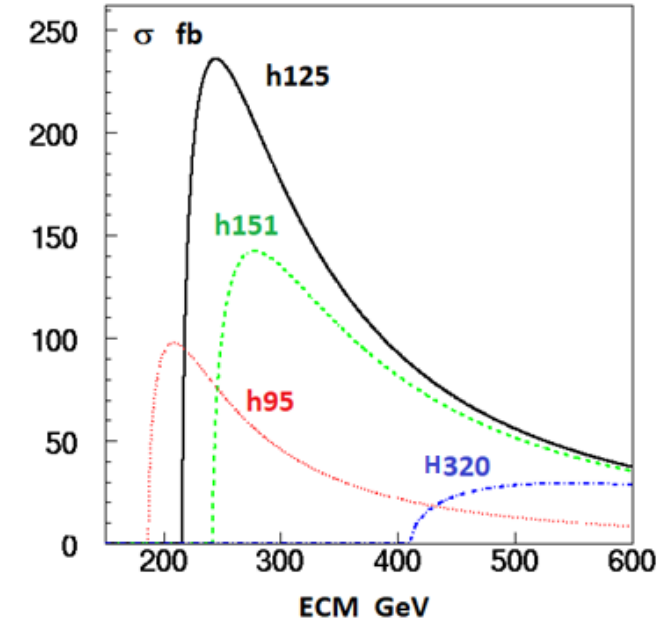

- $h(125)=0.58(\phi 1+\phi 2)+0.58H'1$
- $v1 =-30 v2=102 u=70 \text{ GeV } v=174 \text{ GeV}$
- Type I Yukawa $Y_i/SM=x_i2*mt/v2$
- $H_{i_{WW}}/SM=(x_i1v1+x_i2v2)/v+(2x_i3+2v2x_i4)u/v$
- Neutral scalars do not coincide with GM isospin states H1, H3 and H5
- Coloured squares have unmeasured couplings which can be **predicted** by this method
- **H125** has a **large mixing with H⁰'1** as predicted by PM of [1807.10660](#)
- **H650** dominated by **doublets** does not belong to fiveplet
- **H320** belongs to fiveplet but differs from H05 therefore couples to h125h125
- H320->ZZ has a width $\sim 5 \text{ GeV}$ subdominant to $\Gamma_{H320 \rightarrow AA} \sim 100 \text{ GeV}$
- Predicts $\mu_{95\gamma\gamma}$ and $\mu_{125} \sim 1$ while ATLAS+ CMS measure $\mu_{95\gamma\gamma}=0.27 \pm 0.1$ [2302.07276](#) and $\mu_{125} \sim 1$ implying that **charged scalar** contributions act very differently

An extra H+ ?

- An e-GM scheme requires an extra H+ related to H(650)
- By analogy with $H(650) \rightarrow A(420)Z \rightarrow ttZ$, one expects that **$H+ \rightarrow A(420)W+ \rightarrow ttW+$**
- An inclusive search for heavy jet-jet masses associated to a high pT lepton provides such a candidate [2001.04770](#)
- ATLAS and CMS observe an excess in the inclusive measurement of $ttW+/-$ [2401.05299](#)
- Seems to proceed through ZW fusion to explain the charge asymmetry ($p \rightarrow u \rightarrow W+$: factor 2)
- One should therefore observe $H+ \rightarrow ZW$
- No such effect in ttZ , which is not yet understood

e+e- collider reach

- Final states are complex modes (\sim SM $t\bar{t}H$) requiring the **highest \mathcal{L}** and an **almost ideal detector with forward coverage for b jet ID**
- ILC would provide **8000 fb-1 at 1 TeV**
- **H(650)** mainly produced through VBF (beam polarisation allows a factor ~ 2 gain, not included) benefits from an increased energy
- A(420) and A(130) can be seen through cascades like $H(650) \rightarrow ZA(420)$, $H+(375) \rightarrow A(130)W+$, $H(320) \rightarrow A(131)A(131)$
- Using an **e-e- collider** one could also produce H^{--} through VBF with polarized beams ~ 100 fb at 1 TeV
- Circular machine can access to h95, h151 and H+(130)

Conclusions

- $H(320) \rightarrow h(125)h(125)$ should contribute to the $h^* \rightarrow hh$ SM measurements
- A global interpretation based on GM+SR predicts an immediate **triple discovery** for A(420), A(151), H(320)
- The table of **e-GM isospin states** can be filled with the various indications provided by LHC
- The **matrix method** shows that the neutral candidates, including h(125), strongly differ from the isospin pure states predicted by GM
- Evidence for a **third H+** in $H^+ \rightarrow ttW^+$ as expected in e-GM
- Read our papers : [2404.09827](#) the most recent
- [2211.11723](#) and <https://indico.cern.ch/event/1253605/>
- [2308.12180](#) constantly updated
- Stay tuned !

Additional slides

Sum Rule I

- **W+W- ->W+W-** Haber et al. in [P.R.D 43 \(1991\) 904-912](#)

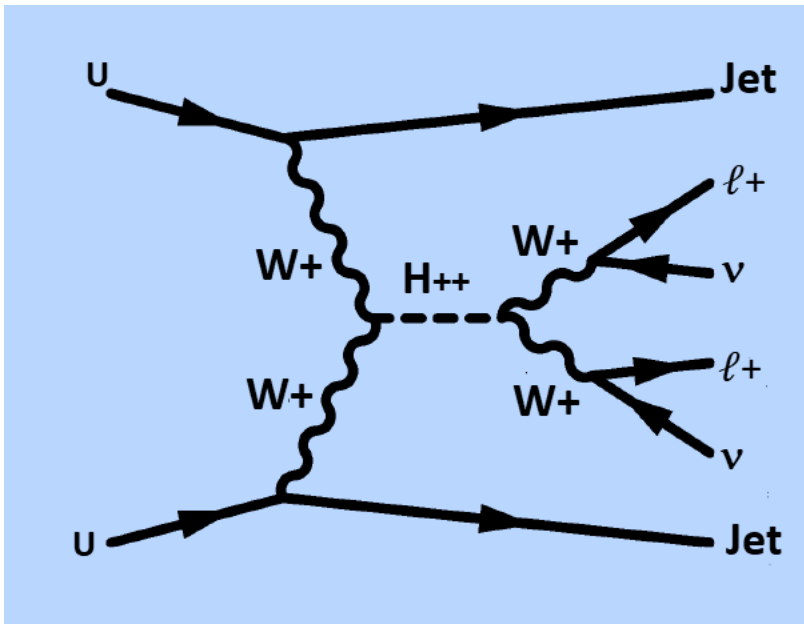

$$g^2(4m_W^2 - 3m_Z^2 c_W^2)^{\rho \simeq 1} \simeq g^2 m_W^2 = \sum_k g_{W^+W^-H_k^0}^2 - \sum_l g_{W^+W^+H_l^{--}}^2$$

- So-far we have been able to measure H(650)W+W- and ([2302.07276](#)) h(95)W+W-
- There are other candidates like h(151) and H(330) where these measurements are unavailable, but we have ideas on how to deal with them ([2308.12180](#) and <https://indico.cern.ch/event/1253605/>)
- H(650) alone forces to have a contribution of H++->W+W+ with a coupling $\sim \text{SM} = gm_W$

First hint for H_{5}^{++}

- Recently at the Belgrade ATLAS meeting: $H_{5}^{++}(450) \rightarrow W^{+}W^{+}$
- LHC is ideally suited for this measurement:

- 3.2 s.d. local, 2.5 s.d. global
- The reconstruction efficiency of CMS is a factor 2 below that of ATLAS [2312.00420](#)

Sum Rule II

- **W+W- -> ZZ** allows a similar SR

$$\frac{g^2 m_Z^4 c_W^2}{m_W^2} \rho \simeq 1 \simeq g^2 m_Z^2 = \sum_k g_{W+W-H_k^0} g_{ZZH_k^0} - \sum_l g_{W+ZH_l^-}^2$$

- This forces a strong coupling for **H+ -> ZW+** which should be observed at LHC
- Note that this result depends on the **signs** of the coupling constants which are not known from present measurements
- h95ZZ is known from LEP2 (but not its sign !)

Evidence for $H^+ \rightarrow ZW^+$

- Coincident excesses at $m_{H^+} \sim 375$ GeV for ATLAS & CMS
- **ATLAS** claims 2.8 s.d. local
- In GM $H^+ H^+$ and $H^+ H^0$ are mass degenerate which is almost true (see for e-GM [2111.14195](#))
- $H(650)$ cannot fulfil the requirements of a neutral candidate of H^+ but $H(320)$ is more appropriate

Model independent results

- From these and the SR, one can deduce the total cross section, the elastic BR and the total widths as given in the following table:

Channel	σ_{VBF} fb	σ_{VBF} VV fb	BR(VV) %	Γ_{tot} GeV
H ⁺⁺ (450)	830	75	9 ± 4	160
H ⁺ (375)	810	125	15 ± 8	80

- These predictive results only rely on the validity of the sum rule approach, which seems legitimate given that VV final states at the LHC energy scale agree with the SM predictions
- They call for lighter charged scalars to provide VH and HH contributions

GM interpretation

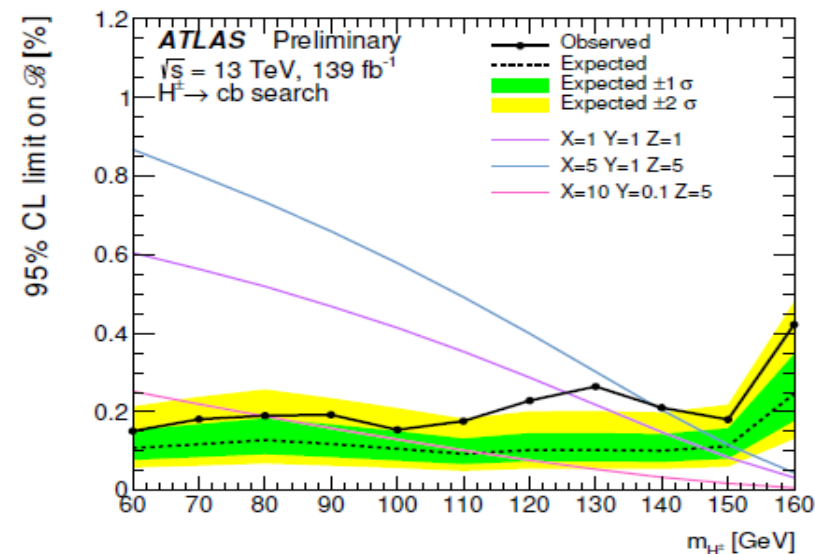

- Quantitatively, SR predicts $\Gamma_{H^{++} \rightarrow W^+W^+}$ and the measured cross section allows to deduce the BR(W+W+) and the total width $\Gamma_{H^{++} \rightarrow W^+W^+} / \text{BR}(W^+W^+)$

Channel	u GeV	s_H	BR(VV) %	BR(VH) %
H ⁺⁺	70 ± 12	0.80 ± 0.1	9	12.5
H ⁺	80 ± 13	0.90 ± 0.2	15	17

- u=70 GeV** comes as a surprise: usual lore is BR(W+W+)=1 and u<25 GeV
- This large value is inconsistent with models with only one triplet ([2312.17314](#)) requiring u much smaller to fulfill $\rho \sim 1$
- BR(W+W+)~10% requires other modes like H'+W+ or even **H'+H'+** (ZH'+ for H+)
- A light (or several) H'+ predicted**

A light H'^+ ?

- There are few indirect hints for this
- B decays into $D\tau$ and $\Lambda\tau$ are reduced by 1.6 and 1.4 s.d. [2305.00614](#) suggesting $m_{H^+} \sim 200$ GeV
- ATLAS has searched for $t \rightarrow bH^+ \rightarrow bbc$ and found a 3 s.d. local (2.5 global) excess around 130 GeV [2302.11739](#)
- Not allowed in 2HD models for type II [1702.04571](#) but allowed for $\tan\beta > 2$ in type I
- One predicts A mass degenerate which can feed into $H^+(375) \rightarrow AW^+$ (could be $A(151)$ seen into 2γ)
- Works quantitatively to explain the observed BR of H^{++} and $H^+(375)$ into $H'^+H'^+$ and H'^+A
- Good news for circular colliders

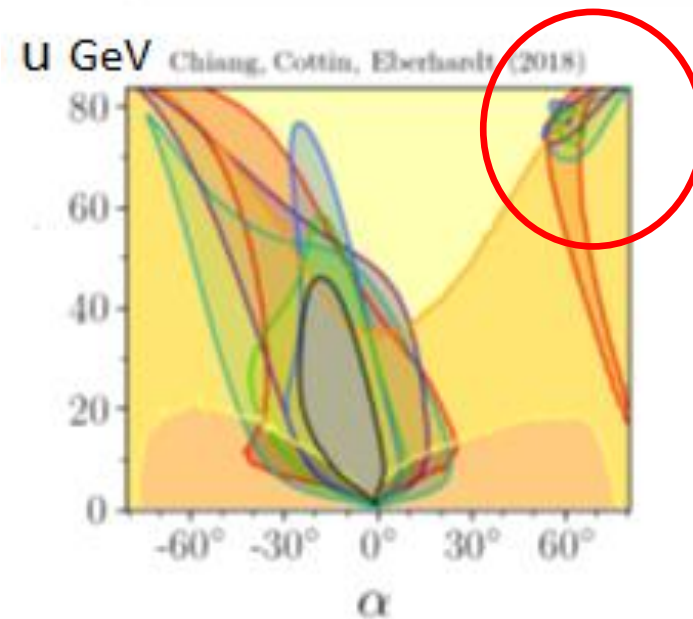

An extra H+ ?

- An e-GM scheme requires an extra H+ related to H(650)
- By analogy with $H(650) \rightarrow A(420)Z \rightarrow ttZ$, one expects that $H+ \rightarrow A(420)W \rightarrow ttW+$
- An inclusive search for heavy jet-jet masses associated to a high pt lepton provides such a candidate [2311.04033](#)
- This reaction could be indirectly observed by ATLAS and CMS as an excess in the inclusive measurement of $ttW+$ [2401.05299](#)
- However no sign of an excess in ttZ

Precision Measurements

- $u \sim 70$ GeV deduced from the sum rules seems incompatible with PM
- There is however a GM solution with **large** $\alpha \sim 60^\circ$ and $u = v_\xi = v_\chi = 75$ GeV which satisfies PM for $h(125)$
- Implies that h can have a **large triplet component** still passing PM
- Not necessarily true for $h \rightarrow hh$ or $Z\gamma$
- $\mu_{95\gamma\gamma} \sim 0.3$ differs from the matrix prediction ~ 1 , perhaps due to the charged Higgs sector while $\mu_{125\gamma\gamma} \sim 1$ could be due to an accidental cancellation

[1807.10660](https://arxiv.org/abs/1807.10660)

The neutral sector in e-GM

- e-GM comprises two doublet fields ϕ_1, ϕ_2 with vev \mathbf{v}_1 and \mathbf{v}_2 and two triplet fields χ, ξ with the same vev \mathbf{u}
- For the neutral sector one writes:

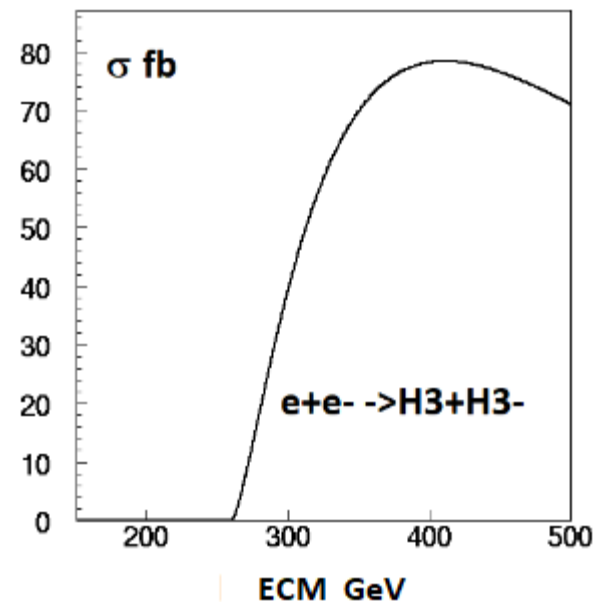

$$\begin{pmatrix} h_{95} \\ h_{125} \\ H_{320} \\ H_{650} \end{pmatrix} = \mathcal{X}_{4 \times 4} \begin{pmatrix} \phi_1^0 \\ \phi_2^0 \\ \chi^0 \\ \xi^0 \end{pmatrix}$$

- where the matrix is 4X4 unitary **real** (no CPV) with $16-4-6=6$ **free parameters** requiring the **unitary vectors** to be **orthogonal**
- In total there are 6+3 (v_1, v_2, u) free parameters and 7 observables from LHC measurements, u from SR + constraint $v_1^2+v_2^2+4u^2=(174 \text{ GeV})^2$
- One needs to choose between various **Yukawa coupling patterns** and we find that **type I** (all fermions having the same coupling) gives a reasonable agreement with the data

H(320) as a partner of H++ ?

- The **H5 multiplet** containing H++ needs to be completed by a neutral scalar, which cannot be H(650) which is doublet dominated
- Given its mass, H(320) seems appropriate and its dominant content in triplet fields (see matrix) reinforces this hypothesis
- However, its decay into bbbb interpreted as h(125)h(125) seems to violate GM
- Note that h(125) and h(95) also carry triplet components which allows H(320)->hh
- H(320) most probably decays into **A(151)A(151)** which feeds into bbbb, experimentally indistinguishable from hh
-

Collider reach

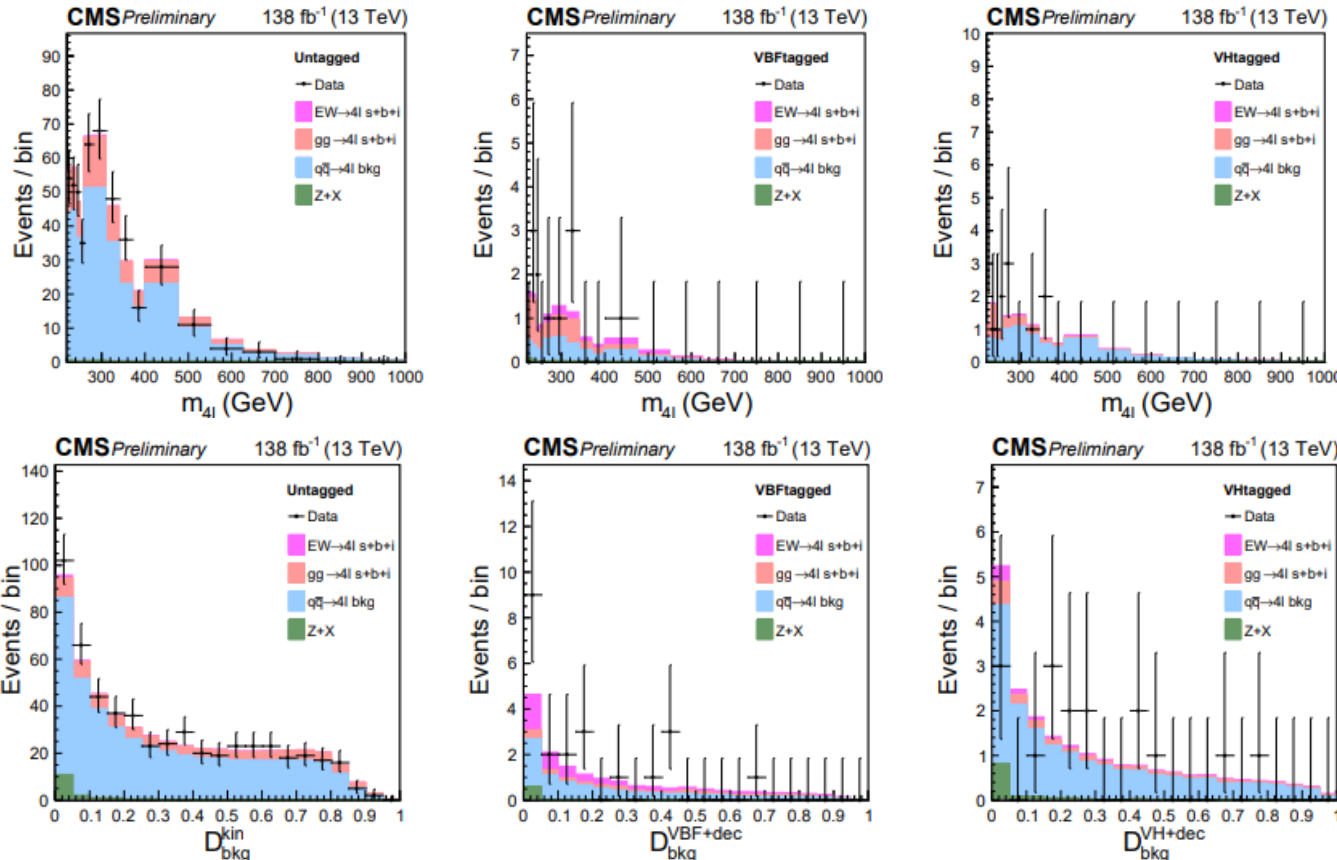

- Final states are complex modes (\sim SM $t\bar{t}H$) requiring the **highest \mathcal{L}** and an **almost ideal detector with forward coverage for b jet ID**
- ILC would provide **8000 fb-1 at 1 TeV**
- **H(650)** mainly produced through VBF (beam polarisation allows a factor ~ 2 gain, not included) benefits from an increased energy
- A(420) and A(130) can be seen through cascades like $H(650) \rightarrow ZA(420)$ and $H+(375) \rightarrow A(130)W+$
- Using an **e-e- collider** one could also produce H^{--} through VBF with polarized beams ~ 100 fb at **1 TeV**
- Circular machine can access to h95, h151 and H+(130)

Results from CMS

[CMS-PAS-HIG-21-019](#)

- Selecting a scalar solution in $ZZ \rightarrow 4l$, $D_{\text{bkg}} > 0.6$, CMS finds:

Tensor decay in ZZ

- No sign of an excess at ~ 650 GeV in this subsample
- A tensor resonance, fwd peaked, removed by this selection ?

Bulk KK graviton ?

- [2310.01643](#)

k/Mplanck

-

(just for illustration since $e+e- \rightarrow G_{KK} \rightarrow \mu+\mu-$ is unlikely to couple to G_{KK})

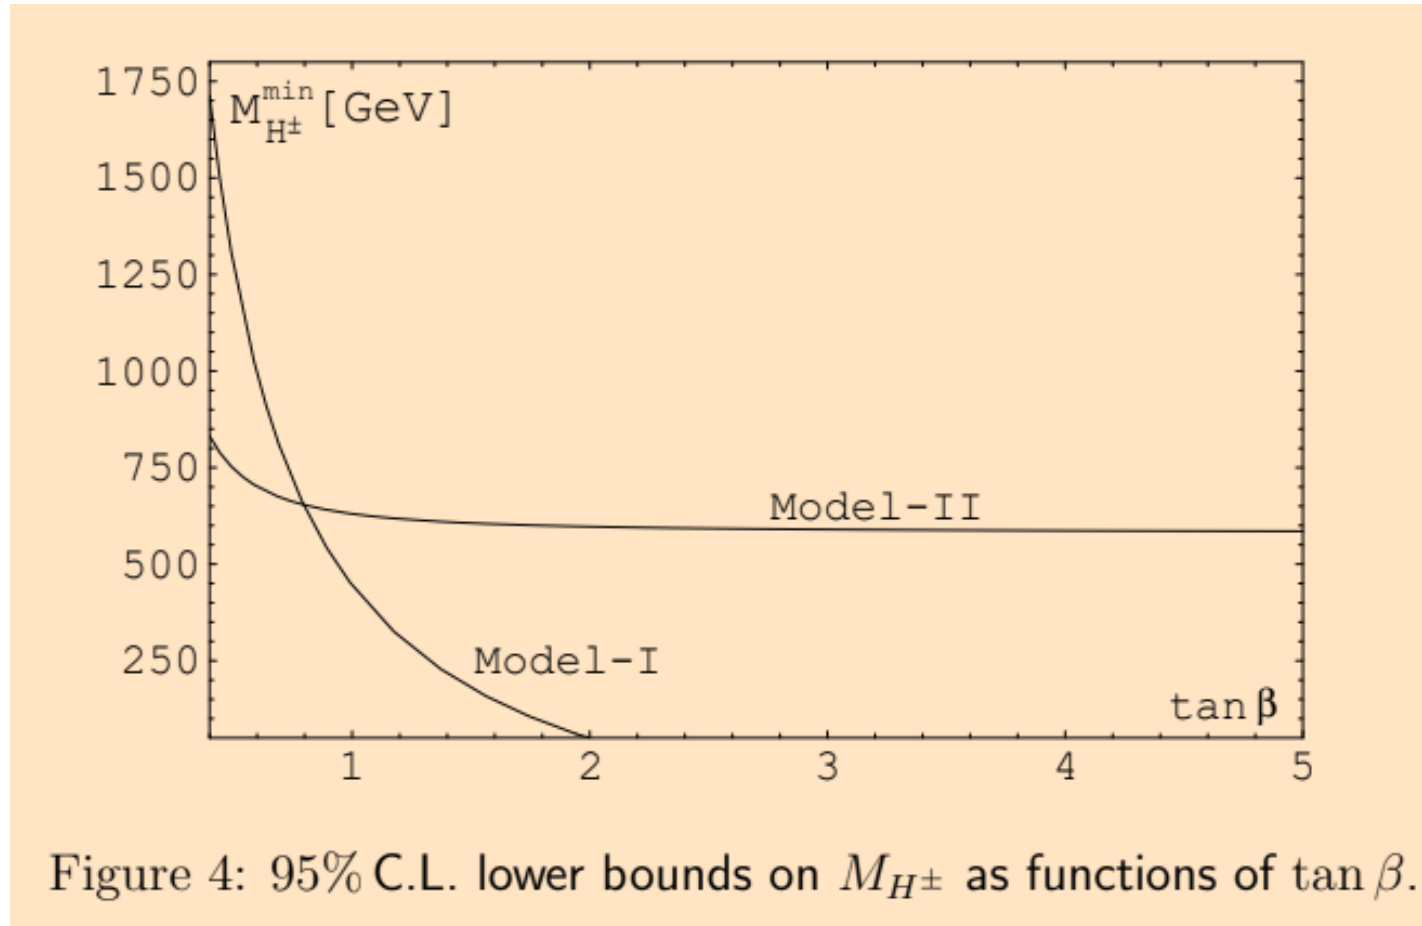

[9909255](#) $e+e- \rightarrow G_{KK}(600) \rightarrow \mu+\mu-$ versus

$b \rightarrow s\gamma$ constraint on m_{H^\pm}

- Light H^\pm excluded for 2HDM II, not for 2HDM I with $\tan\beta > 2$ [1702.04571](#)

How to derive the missing couplings ?

- There are indications for several neutral scalars candidates on the market, with unknown couplings to WW/ZZ
- Can one derive them taking into account the present measurements ?
- The answer seems positive assuming there is no CP violation and using available measurements

1st indication : H→ZZ into 4 leptons

- The **cleanest channel** for discoveries
- From a combination of published histograms [1806.04529](#) with 113.5 fb⁻¹ from **CMS (2/3)** and **ATLAS (1/3)** one observes a peak with $M_H \sim 660$ GeV $\Gamma_H \sim 100$ GeV, $\sigma \sim 90 \pm 25$ fb with s/b=46/20 ~ 3.8 s.d. local significance (5.8 Bayesian), 2.8 s.d. global
- With 139 fb⁻¹, with **sequential cuts**, an excess is observed at the same mass, s/b=9/2 ~ 2.1 s.d., for **VBFBR(ZZ)→H(660)→ZZ $\sim 34 \pm 20$ fb** (~ 2 times smaller with a **MVA analysis**) [2009.14791](#) and 3 sd **150 ± 60 fb** for **ggFBR(ZZ)**
- The MVA analysis gives **ggFBR(ZZ) < 50 fb** MVA + **ℓ+ℓ-νν**
- CMS analyses into four leptons are not yet published
- These results call for a combination of both analyses before one can draw a valid conclusion
- Could stop here but...

CAVEAT on H(650)->ZZ

- CBA with 4 leptons indicates an excess $\sim 3.5\sigma$ combining ggF and VBF
- This translates (guesswork) into $ggF(BR(ZZ)) \sim 150 \pm 60$ fb
- Adding $l+l-\nu\nu$ one sets an upper limit $ggF(BR(ZZ)) < 50$ fb assuming a 100 GeV width
- In "tension" with above result

Historical progress of H(650)

Steps	Mode	Origin	Local sd	Remark	Global sd
0	ZZ->4 ℓ	ATLAS+CMS from [7]	3.8	ATLAS+CMS 113.5 fb ⁻¹ Defines mass & width	2.8
1	ZZ->4 ℓ	From ATLAS	3.5	From histogram	3.5
2	WW-> $\ell\nu\ell\nu$	From CMS	3.8	Official statement	5
3	h(95)h(125)->bb $\gamma\gamma$	From CMS	3.8	Official statement	6.1

Evidence for $VBF \rightarrow H(650) \rightarrow W+W- \rightarrow \ell\ell\nu\nu$

ggF has a large top background even after b-jet vetoing and using μe (against DY)

Wide signal with $\pm 50\%$ mass resolution

$VBF \rightarrow H(650) \rightarrow \ell\ell\nu\nu$ allows to see a signal

This **VBF** cross section $\sim 160 \pm 50$ fb, close to SM, is ~ 3 times larger than $VBF \rightarrow ZZ$, inconsistent with **GM** which predicts for the scalar **H5** $WW/ZZ=0.5$

2 HD excluded (blue line) $h(125)WW$ predicts $\sin^2(\alpha-\beta) \sim 0.97 \pm 0.09$ meaning that $H(650)WW \sim \cos^2(\alpha-\beta) \sim (0.03 \pm 0.09)SM$

Both GM and 2HD excluded !

An attempt from ATLAS does not reach the same sensitivity (only μe) [ATLAS-CONF-2022-066](#)

μe

CMS PAS HIG-20-016

Table 3: Summary of the signal hypotheses with highest local significance for each f_{VBF} scenario. For each signal hypothesis the resonance mass, production cross sections, and the local and global significances are given.

$\mu+\mu^-$

ggF \rightarrow W+W-

VBF W+W-

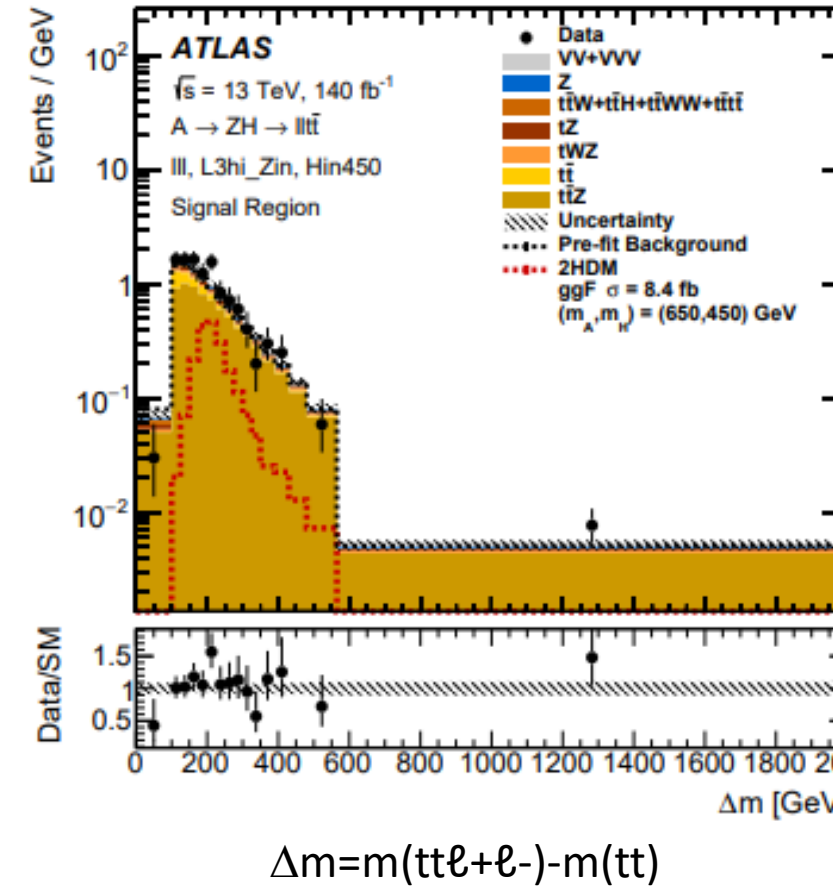

Evidence for $gg+VBF \rightarrow H(650) \rightarrow Y(90) + h(125) \rightarrow bb + \gamma\gamma$

- 3.8 s.d. for $m_H=650$ GeV and $m_Y \sim 90$ GeV shown at ICHEP22
- Mass resolution on Y does not allow to distinguish between Z and h(95) which is by now a “good old friend”
- CP says that bb cannot come from $Z \rightarrow bb$ but could be **h(95)** which is another scalar candidate seen in 3 channels [2203.13180](#) + [2302.07276](#)
- The cross section is dominant over all other indications **$\sim 190+90-70$ fb** but it includes ggF+VBF
- Also interpreted by CMS as a **tensor particle**

Evidence for $H(650) \rightarrow A(450)Z$

- ATLAS sees a 2.85 s.d. excess in ttZ in $A(650) \rightarrow H(450)Z \rightarrow tt\ell+\ell-$ [2311.04033](#)
- Also compatible with $H(650) \rightarrow A(450)Z \rightarrow tt\ell+\ell-$
- Reinforces the case for $H(650)$
- The CP=-1 candidate $A(420) \rightarrow tt$ [1908.01115](#) is compatible given the poor mass resolution
- A third observation was in $A(420) \rightarrow H(320)Z \rightarrow hhZ$ [ATLAS-CONF-2022-043](#)
- In this context, there is no need to invoke the LE criterion which would justify the word ‘insignificant’ for this new indication easily accommodated within GM

Evidence for H(320) and A(420)

- ATLAS has observed **A(420)->ZH(320)** with H(320)->h(125)h(125)->bbbb
- The bb mass resolution is too poor to exclude contributions from h(95) or A(130)
- The significance is 3.8 s.d. local [2210.05415](https://arxiv.org/abs/2210.05415)
- This decay sits close to the kinematical limit meaning that H(320) could be heavier and complete the GM **H5 multiplet**, together with H+(375), H++(450)
- Recall that H(320)->hh is forbidden only if h is a pure singlet and H pure triplet, which is not the case
- Note finally that this indication constitutes the **3d evidence** for a CP odd A, together with A->tt and H(650)->AZ

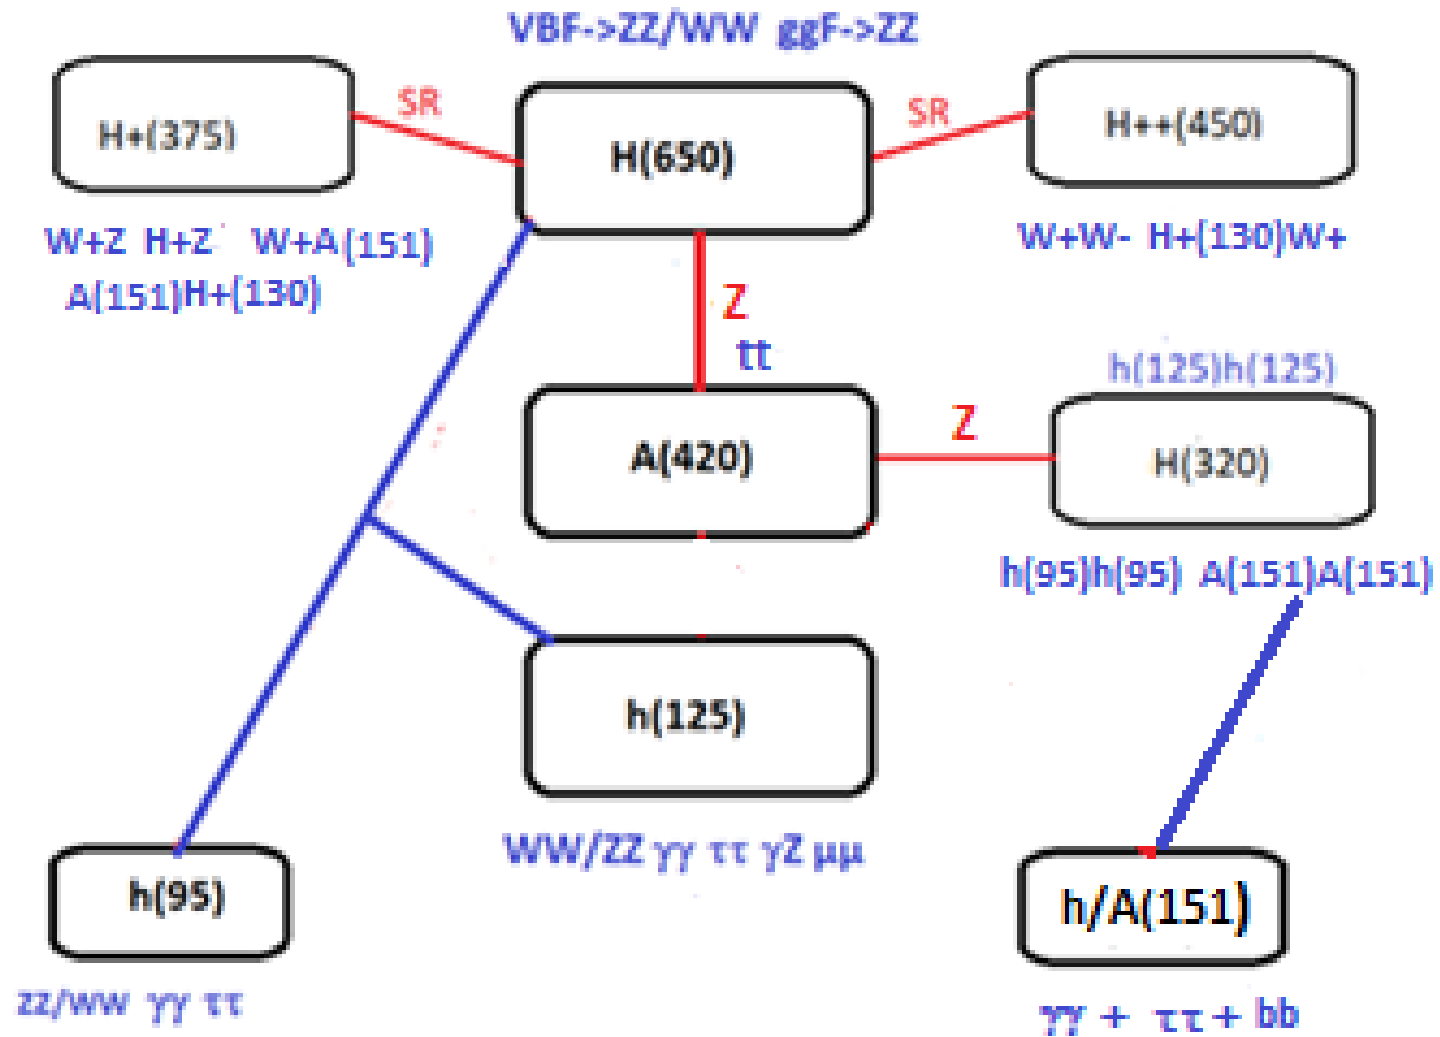

Evidence for $h/A(151) \rightarrow \gamma\gamma + \text{tag}$

- A second $\gamma\gamma + Z\gamma$ peak appears when requiring extra tag E_{miss} or b jet
- 2109.02650 claims ~ 4 sd by combining ATLAS and CMS data
- GM predicts that $ggF \rightarrow H(320)$ has a cross section of 2000 fb, 2/3 going into $A(151)A(151)$ with $A \rightarrow bb$, $\tau\tau$ providing the tagging ingredient
- One predicts $\text{BR}(A(151) \rightarrow \gamma\gamma) \sim 1.3 \cdot 10^{-3}$

SUMMARY OF BSM CANDIDATES

Georgi-Machacek for pedestrians

- Allows $I=2$, H^{++} , without violating $\rho = M^2 w / M z^2 \cos^2 \theta w = 1$ at tree level
- Is achieved by combining 1 isospin doublet (v_ϕ) + 2 triplets, one real the other imaginary, with the same vacuum expectations :
- $$\rho = \frac{\tilde{v}_\phi^2 + 4\tilde{v}_\chi^2 + 4\tilde{v}_\xi^2}{\tilde{v}_\phi^2 + 8\tilde{v}_\chi^2} = \frac{v^2}{v^2 + 4(\tilde{v}_\chi^2 - \tilde{v}_\xi^2)} = 1 \text{ with } v_\chi = v_\xi = u$$
- Predicts a **5-plet** of physical states $H5^{++}$ $H5^+$ $H5^0$ $H5^-$ $H5^{--}$ - **Fermiophobic** only produced by **VBF**
- + **3-plet** $H3^+$ $H3^0$ (CP-odd) \rightarrow **A(400)**
- **Mass degeneracy** inside multiplets usually assumed but **unnecessary** for $\rho=1$ see [2111.14195](#)
- + **Singlets** h and h' mixing angle α

The GM model for advanced

- GM is constituted by one doublet ϕ and two triplets, one complex χ and one real ξ , with the same vacuum expectations to get $\rho=1$
- H1 and H1' have following composition

$$\phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}, \quad \chi = \begin{pmatrix} \chi^{++} \\ \chi^+ \\ \chi^{0*} \end{pmatrix}, \quad \xi = \begin{pmatrix} \xi^+ \\ \xi^0 \\ \xi^- \end{pmatrix}$$

$$Y=1/2 \quad T=1/2 \quad v\phi \quad Y=1 \quad T=1 \quad v\chi \quad Y=0 \quad T=1 \quad v\xi=v\chi \quad \rho=1$$

$$\rho = \frac{\tilde{v}_\phi^2 + 4\tilde{v}_\chi^2 + 4\tilde{v}_\xi^2}{\tilde{v}_\phi^2 + 8\tilde{v}_\chi^2} = \frac{v^2}{v^2 + 4(\tilde{v}_\chi^2 - \tilde{v}_\xi^2)}$$

- Only ϕ
- They form the following physical states, dominantly triplet r
- $s_H=2\sqrt{2}v\chi/v$

$$\begin{aligned} H_5^{++} &= \chi^{++}, \\ H_5^+ &= \frac{(\chi^+ - \xi^+)}{\sqrt{2}}, \\ H_5^0 &= \sqrt{\frac{2}{3}}\xi^0 - \sqrt{\frac{1}{3}}\chi^{0,r}, \\ H_3^+ &= -s_H\phi^+ + c_H\frac{(\chi^+ + \xi^+)}{\sqrt{2}}, \\ H_3^0 &= -s_H\phi^{0,i} + c_H\chi^{0,i}. \end{aligned}$$

$$\begin{aligned} H_1^0 &= \phi^{0,r}, \\ H_1^{0r} &= \sqrt{\frac{1}{3}}\xi^0 + \sqrt{\frac{2}{3}}\chi^{0,r}. \end{aligned}$$

- The physical states are

$$\begin{aligned} h &= \cos\alpha H_1^0 - \sin\alpha H_1^{0r}, \\ H &= \sin\alpha H_1^0 + \cos\alpha H_1^{0r}. \end{aligned}$$

- Common wisdom: the mixing angle α **has to be small** to avoid altering the doublet properties of the SM h(125)
- Also $v\xi=v\chi$ are predicted small while SR says that $v\xi=v\chi=70$ GeV

SGM: a SUSY version of GM

[1308.4025](#)

$$\Sigma_{-1} = \begin{pmatrix} \frac{\chi^-}{\sqrt{2}} & \chi^0 \\ \chi^{--} & -\frac{\chi^-}{\sqrt{2}} \end{pmatrix}, \quad \Sigma_0 = \begin{pmatrix} \frac{\phi^0}{\sqrt{2}} & \phi^+ \\ \phi^- & -\frac{\phi^0}{\sqrt{2}} \end{pmatrix}, \quad \Sigma_1 = \begin{pmatrix} \frac{\psi^+}{\sqrt{2}} & \psi^{++} \\ \psi^0 & -\frac{\psi^+}{\sqrt{2}} \end{pmatrix}$$

$$H_1 = \begin{pmatrix} H_1^0 \\ H_1^- \end{pmatrix}, \quad H_2 = \begin{pmatrix} H_2^+ \\ H_2^0 \end{pmatrix}$$

- GM does not necessarily mean compositeness
- SGM provides all the “goodies” of SUSY:
 - Perturbativity, computability
- EWSB naturally triggered
- M_h predicted with less “tension” on stop masses with extra contributions to RC
- Two doublets as needed to interpret H320 and the ZZ/WW decays of H(650)
- DM candidate
- Complex/rich world with ~ 20 Higgs scalars
