

Exclusive Central Production in Proton-Proton Collisions: from Glueballs to Higgs Bosons

Mike Albrow (Fermilab)

- 1) Background: elastic and hard diffractive scattering
- 2) Single Diffractive Excitation of High Masses (Jets, W, Z) – CDF/D0
- 3) Central Exclusive Production:
 $Higgs, \gamma\gamma, e^+e^-, \mu^+\mu^-, \chi_c(\chi_b), Jet + Jet$
- 4) LHC: Study of Higgs (*iff*) through p+H+p, WW and ZZ.
- 5) FP420: R&D project to make this happen.

Compare & Contrast ISR & LHC

ISR = Intersecting Storage Rings started 1971
First colliding proton beams.

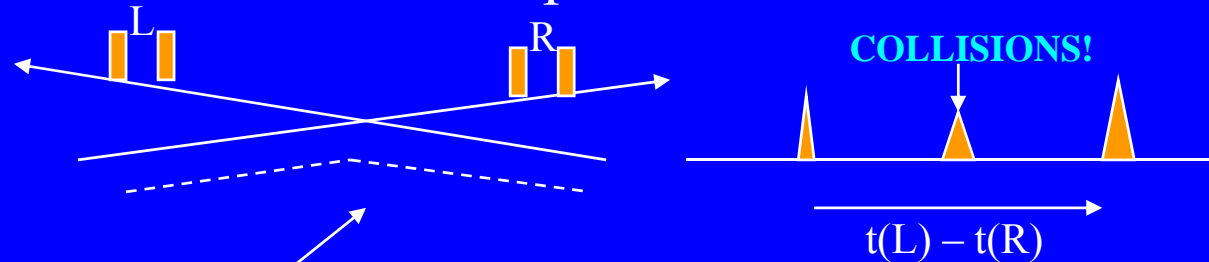

Centre of Mass Energy = 63 GeV

Centre of Mass Energy = 7.4 GeV

Equivalent to beam of 2110 GeV + fixed p target
“Into the realm of cosmic rays!”

First collisions ... no detectors installed! ... put in 4 counters!

Experiment 101

Emulsions on a toy train set!

2006: LHC = Large Hadron Collider

7 TeV = 7000 GeV

7 TeV = 7000 GeV

$\equiv 10^8 \text{ GeV} = 10^{17} \text{ eV}$

cf. cosmic cut off $\approx 10^{20} \text{ eV}$

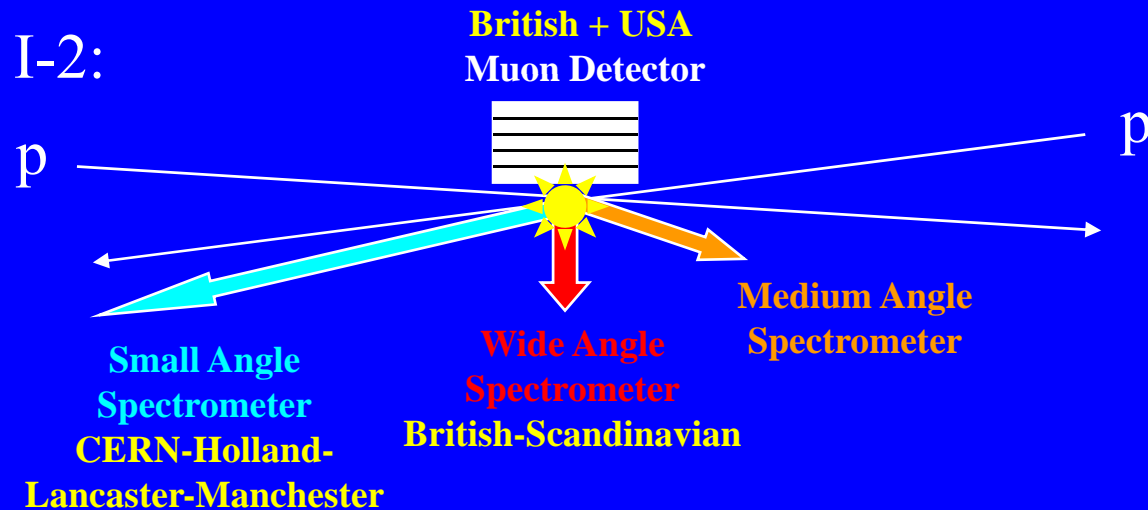

ATLAS being installed. ~ 2000 physicists!

One of four experiments.

Meanwhile, back at the ISR in 1972 ...

Intersection I-2:

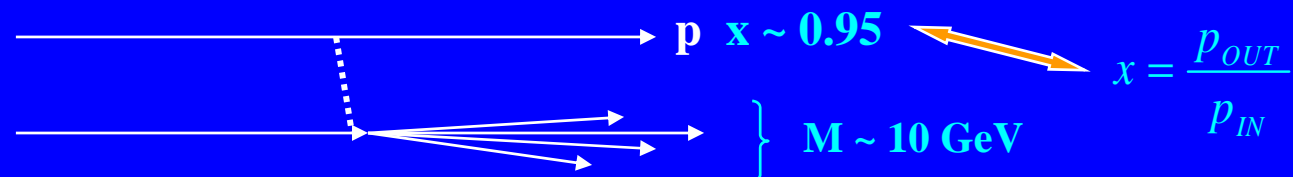

Nobody knew what to do with complete multi-particle ($\sim 10+$) final states.
Study “inclusive” particle production: $pp \rightarrow e, \mu, \pi, K, p \dots + \text{“anything”}$.

Muon Detector: Looking for W ($\sim 3\text{-}4$ GeV!) ... missed J/ψ

Wide Angle Spectrometer: co-discovered high p_T (quark scattering)

Small Angle Spectrometer: discovered high mass (10 GeV) diffraction

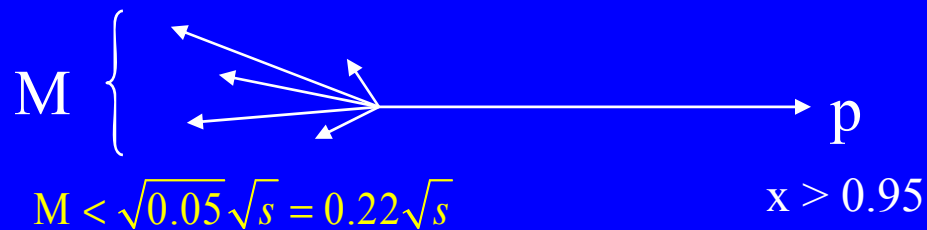

Small Angle Spectrometer: Forward proton spectra

$$x_{Feynman} = \frac{p_L}{p_{beam}}$$

Feynman scaling:

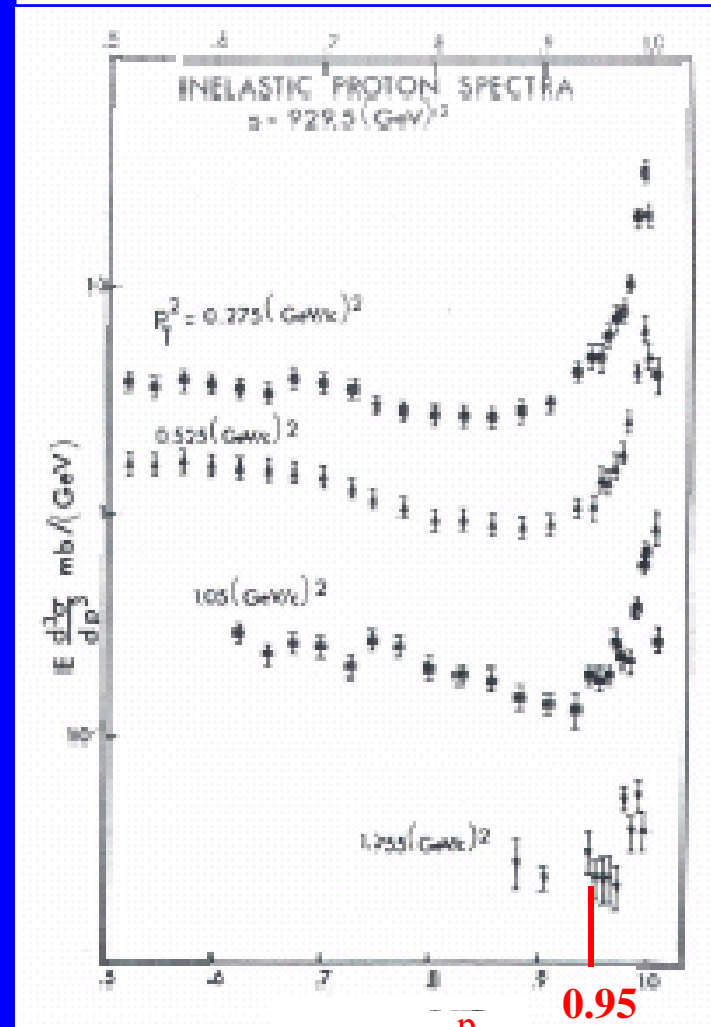

$$E \frac{d^3\sigma}{dp^3} = f(x_F, p_T) \text{ not } \sqrt{s}$$

Discovery of high-x, scaling peak

**M up to about 14 GeV at ISR
440 GeV at Tevatron
3100 GeV at LHC**

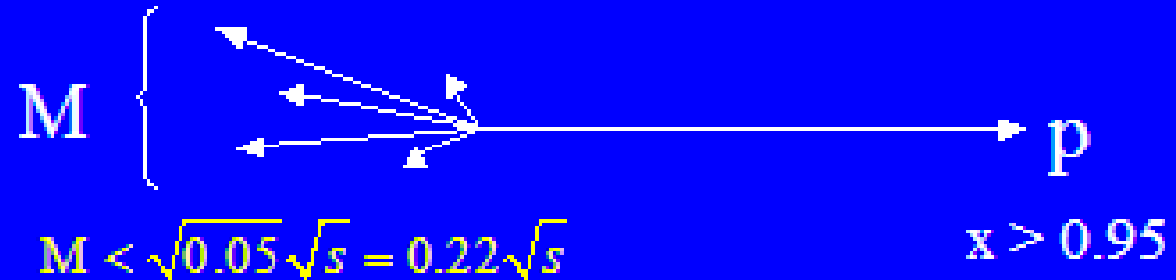

MGA et al., NPB54 (1973) p.6

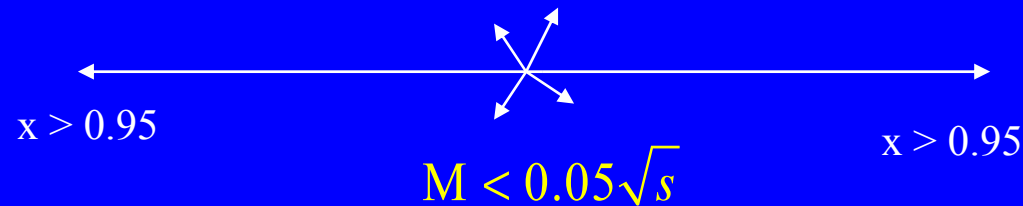

$$x_{Feynman} = \frac{p_L}{p_{beam}}$$

Central Diffractive Excitation

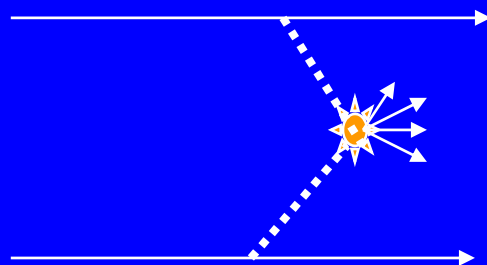

Theoretically, if:

happens, so should:

... both protons coherently scattered

“Vacuum Excitation”

H, WW

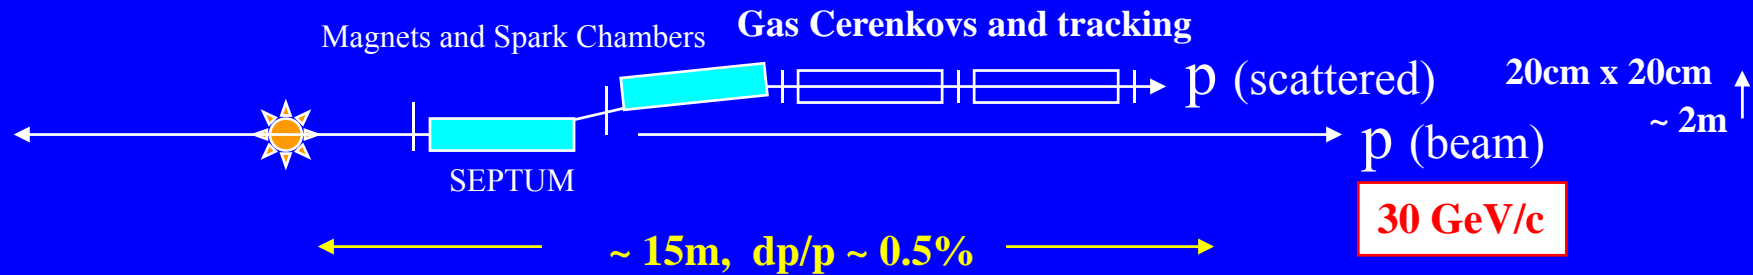

M up to about 3 GeV at ISR
100 GeV at Tevatron
700 GeV at LHC

Exchanged 4-momentum must
have no electromagnetic charge
or strong charge (colour), spin ≥ 1

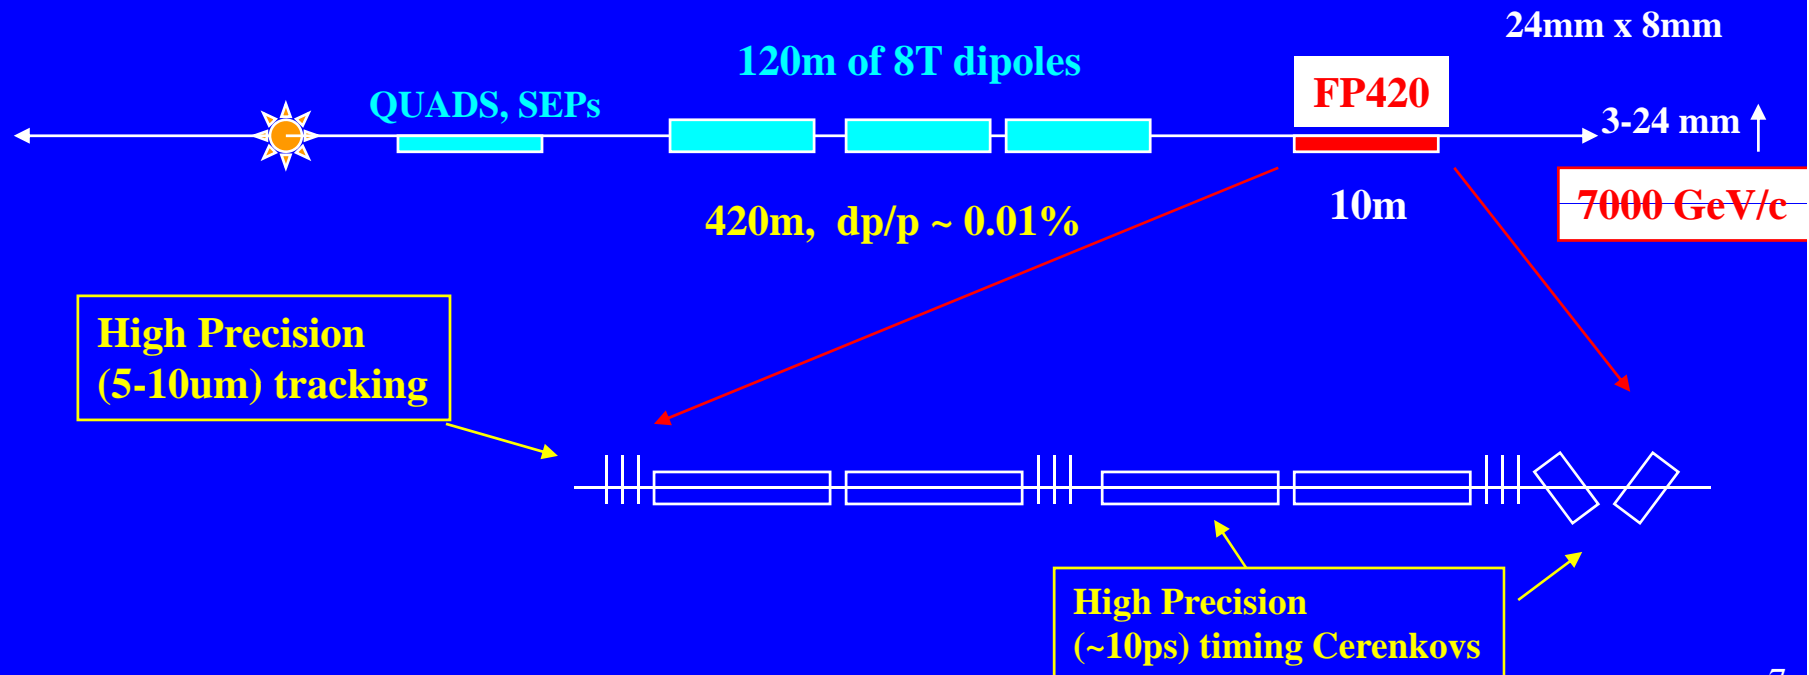

γ or g (+ g, gg)
Central state Quantum Numbers restricted

Forward Proton Spectrometers: ISR \rightarrow LHC

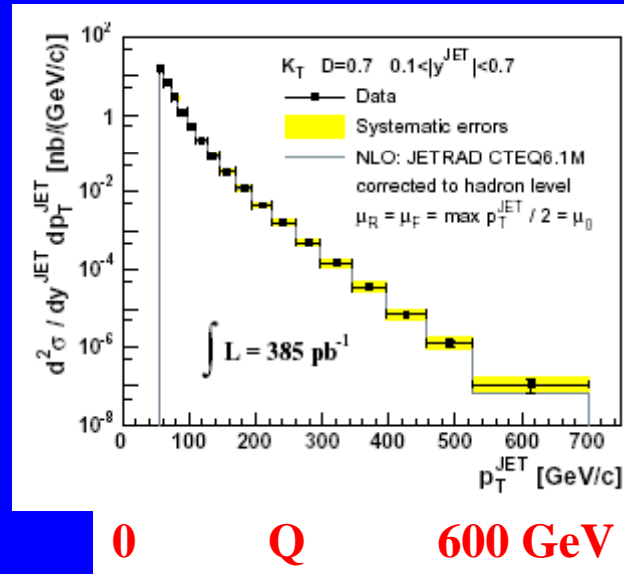

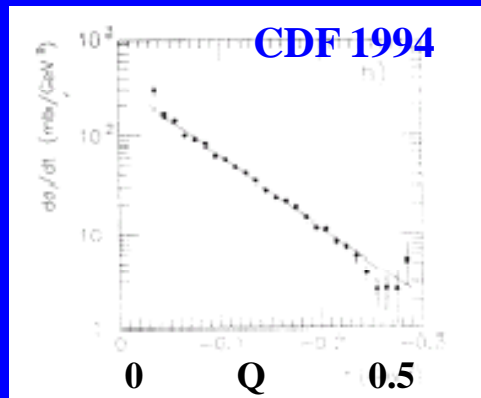

ISR (1971)

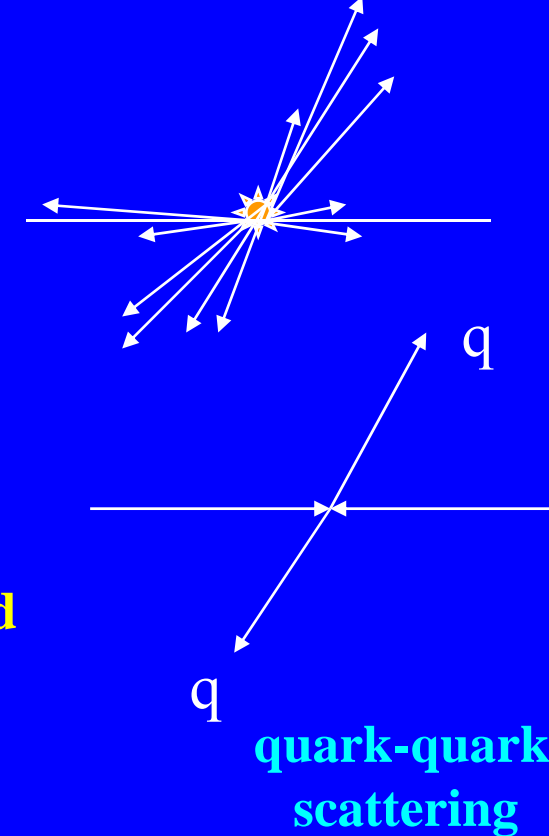

LHC (2009?)

ELASTIC SCATTERING

DI-JET PRODUCTION

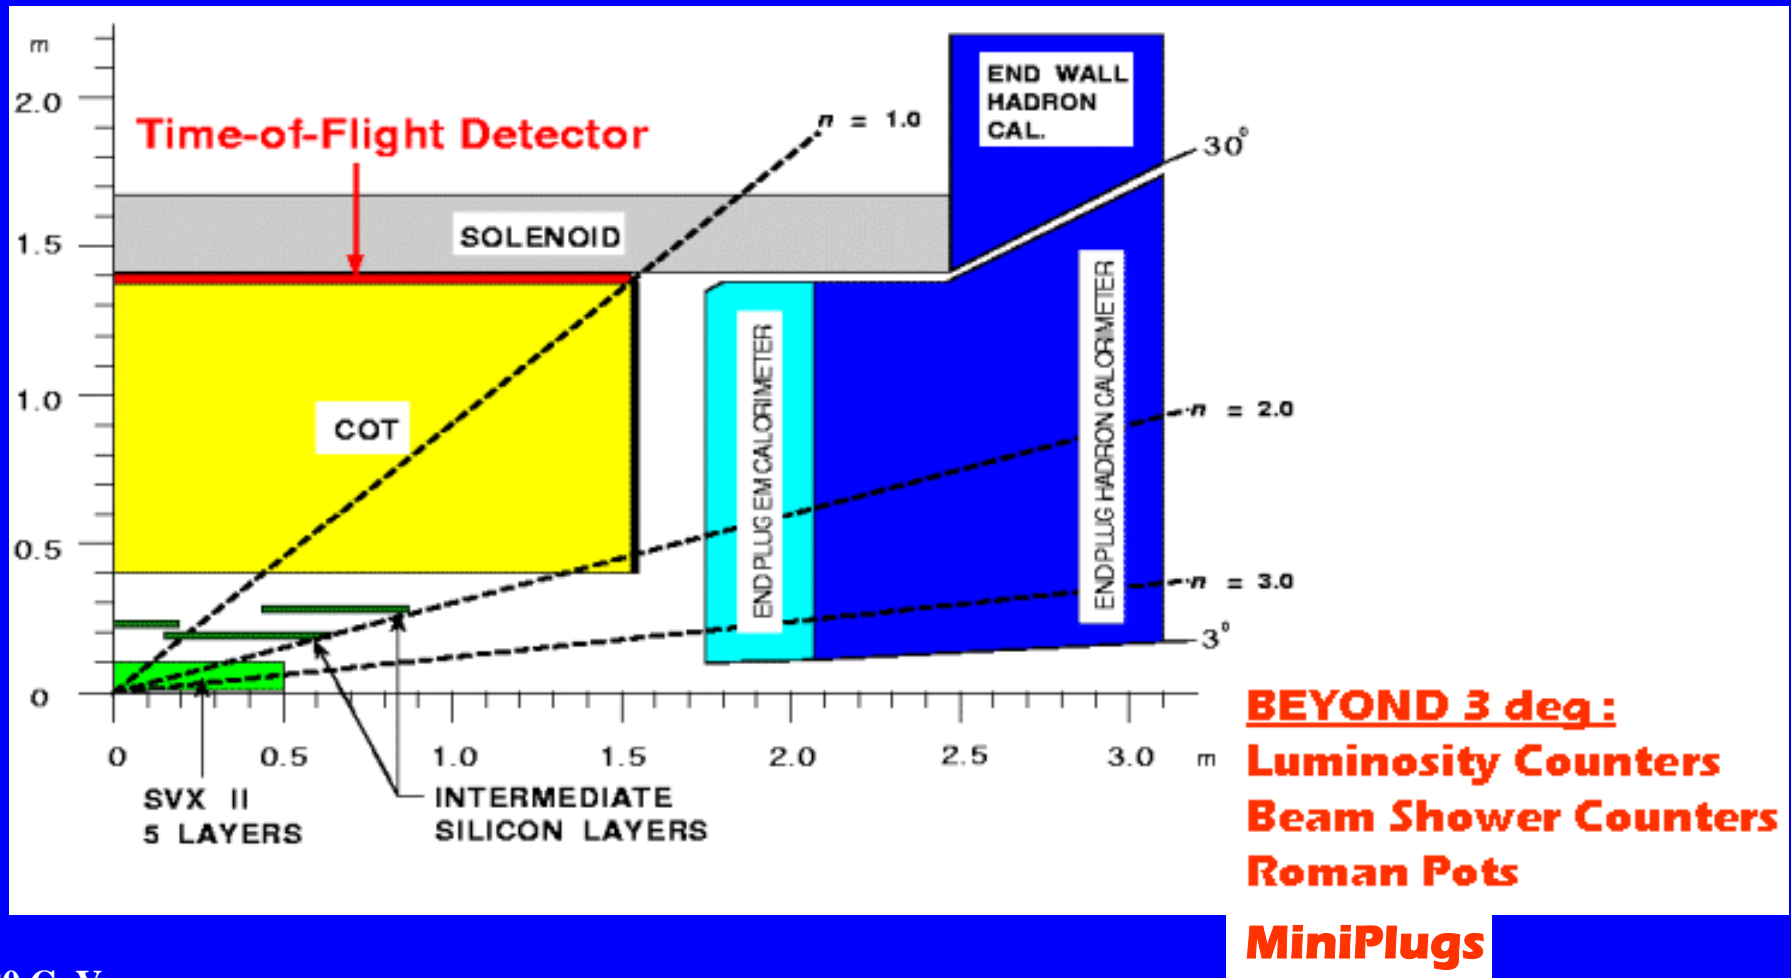

$Q = 4\text{-momentum transferred}$

High Q^2 and low Q^2 together

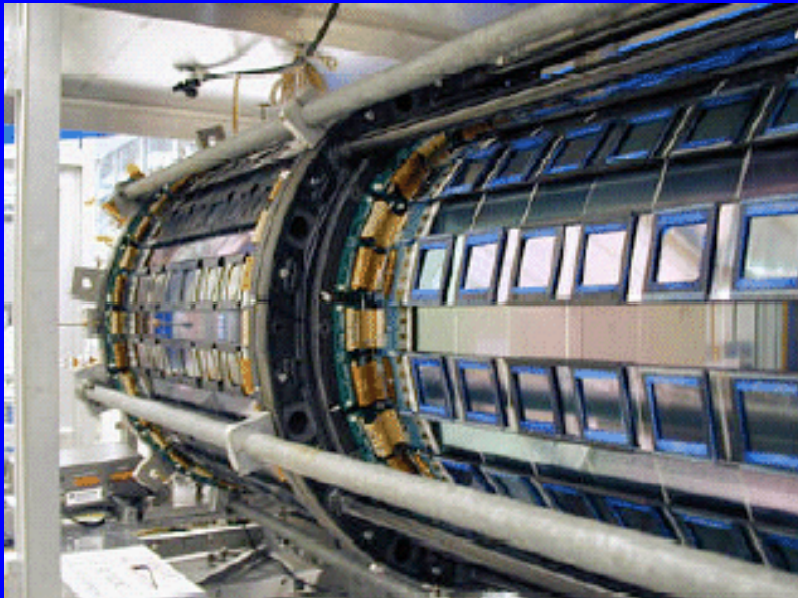

CDF Detector at Fermilab Tevatron

980 GeV
pbar

980 GeV p

Central tracking: Silicon strips & Drift Chamber

~ 720,000 strips,
25um with 50um readout

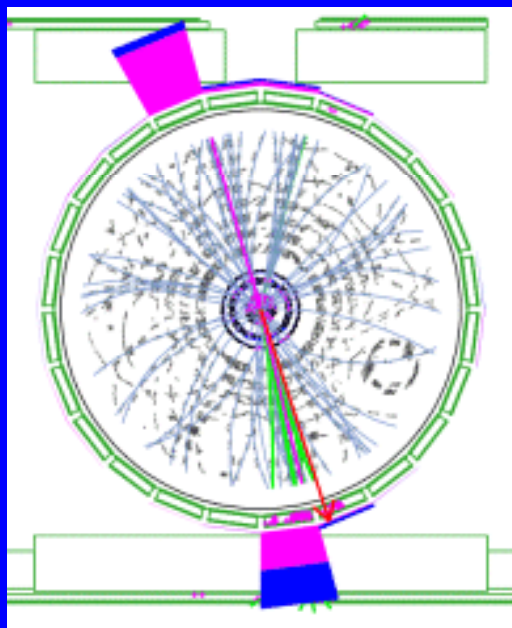

Surrounded by lead/iron
scintillator sandwich calorimeter
for energy measurement

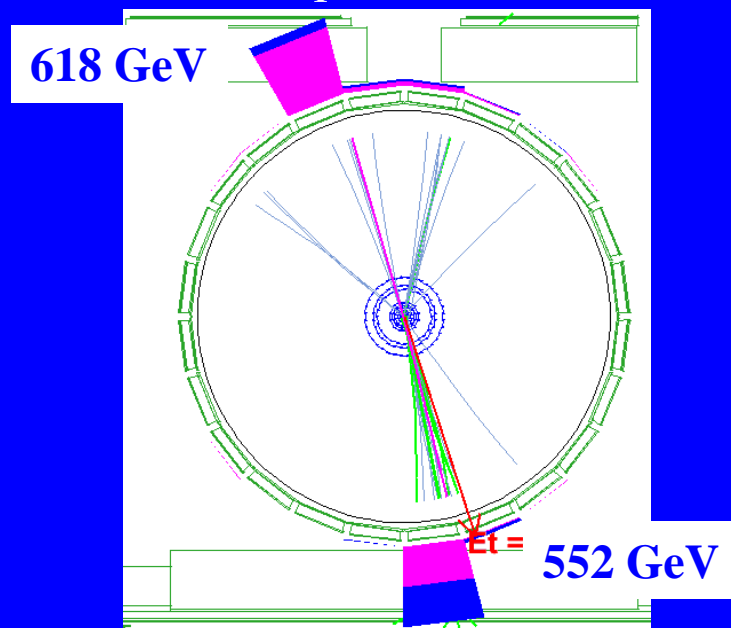

Drift chamber
96 layers → 30,240 s.wires
40 um gold-plated tungsten
ADC and TDC each end
Resolution ~ 150 um/wire

Highest Energy Jets probe smallest distances

All hits/tracks

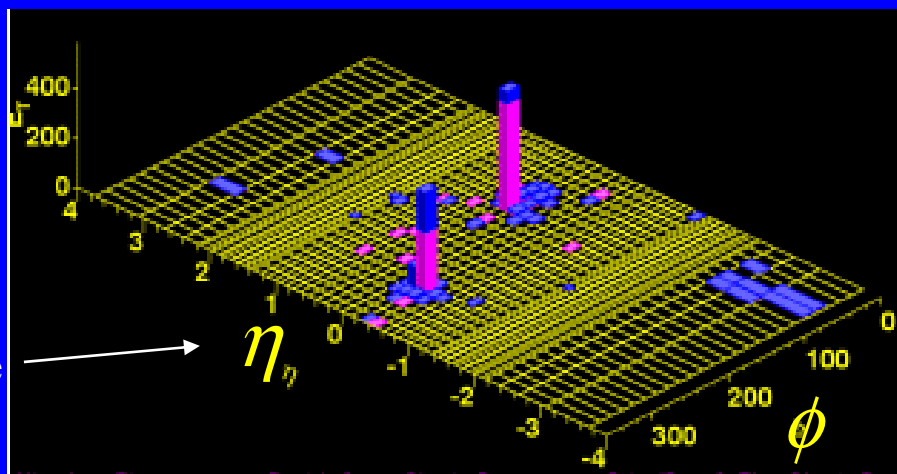

tracks $p_T > 2 \text{ GeV}/c$

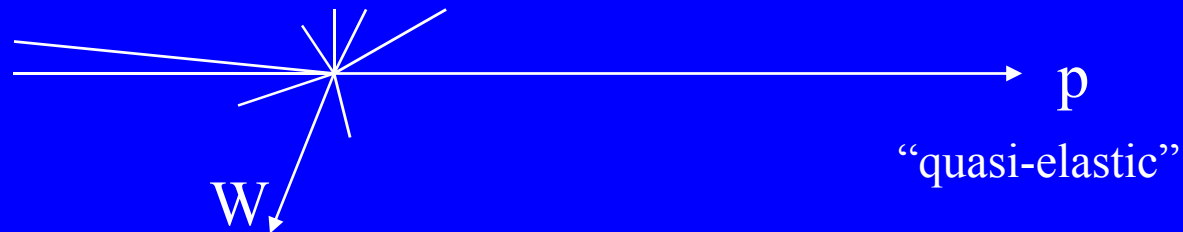

$$\eta = -\ln \tan \left(\frac{\theta}{2} \right)$$

$\sim \log \text{ polar angle}$

$\sim 3 \times 10^{-4} \times \text{proton size}$
(quarks "point-like")

Diffractive W and Z Production

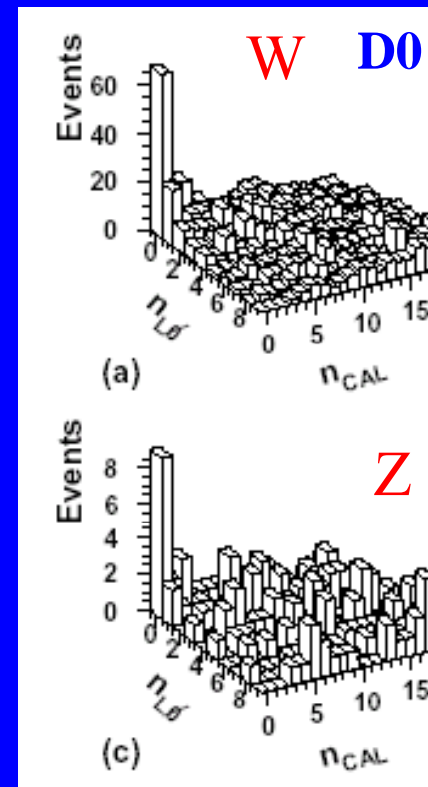

W produced but p “stays intact”

CDF:

$$\frac{\text{Diff. W}}{\text{Non-Diff W}} = (1.15 \pm 0.55)\%$$

D0 sees diffractive W and Z
all consistent with 1% diff./ND

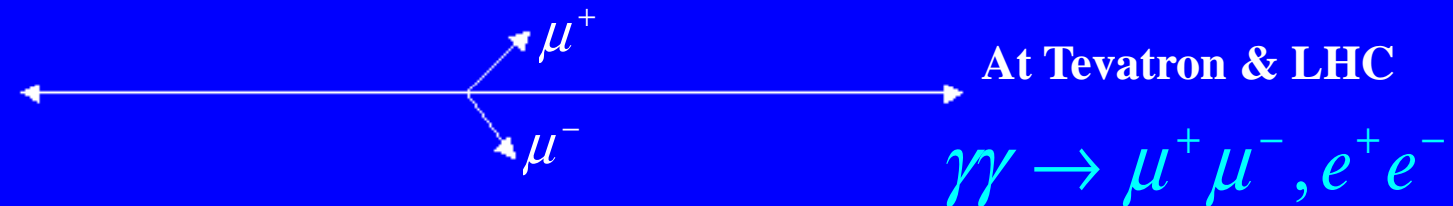

$$\eta(LO) = 2.3 - 4.3$$

$$\eta(CAL) = 3.0 - 5.2$$

Central Exclusive Production

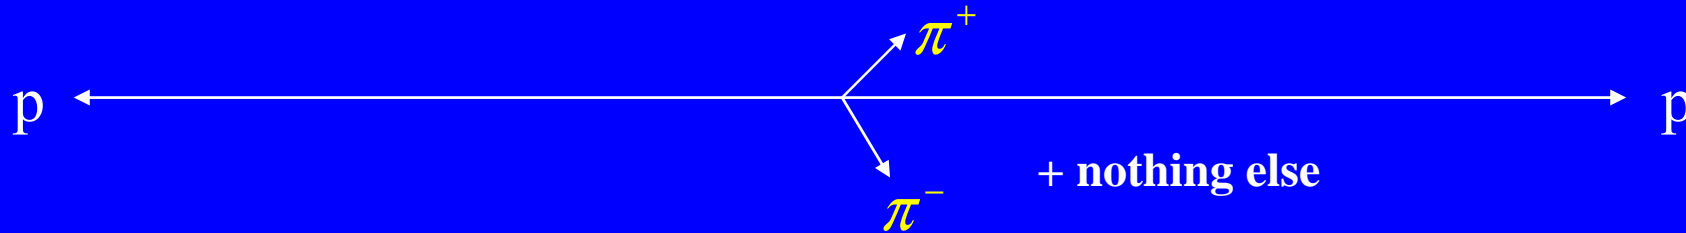

$pp \rightarrow p \quad X \quad p$ where X is *a simple system completely measured*

Low Mass Central Exclusive Production

$pp \rightarrow p \quad X \quad p$
 X fully measured

ISR $\sqrt{s} = 63 \text{ GeV}$

Search for “Glueballs”
 $\{gg\}$ as distinct from $\{q\bar{q}\}$

No ρ , broad $\sigma(600)$?

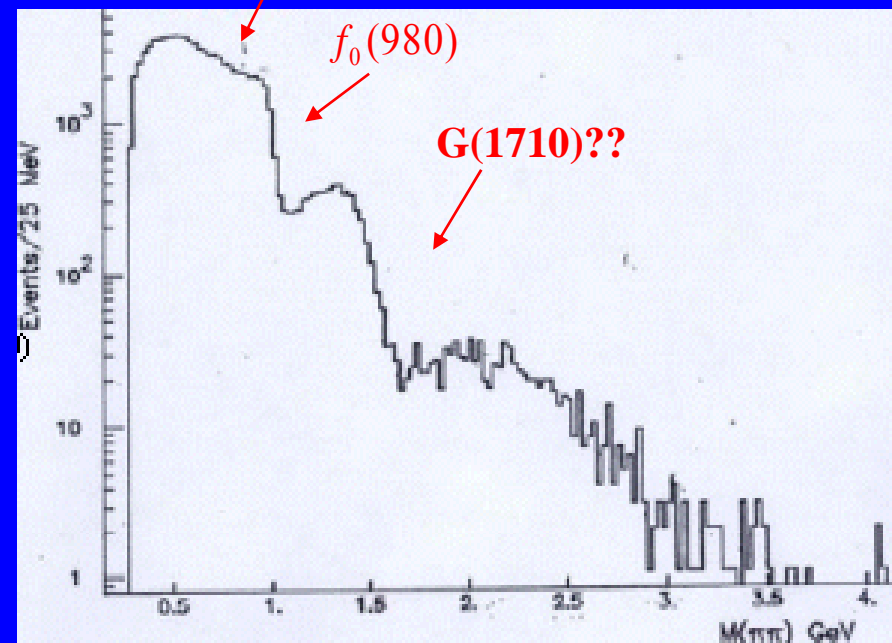

Structures not well understood
 beyond $f(980)$.

Not studied at higher \sqrt{s}

... and

$\alpha\alpha \rightarrow \alpha + \pi^+ \pi^- + \alpha$

coherence!

Central Exclusive Production of Higgs Bosons

Gluon-gluon fusion: main channel for H production.

Another gluon-exchange can cancel color, even leave p intact.

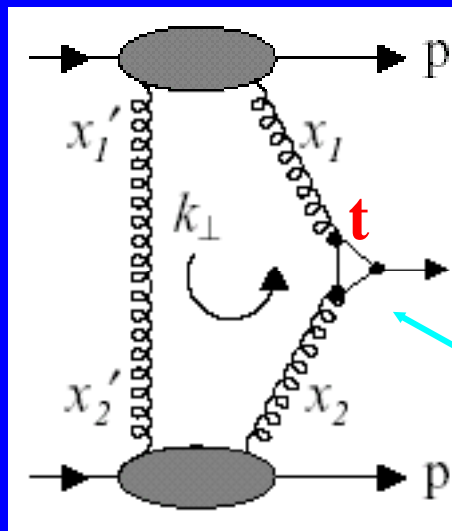

$$p p \rightarrow p + H + p$$

Theoretical uncertainties in cross section.

→ Probably $\sigma(SMH) < 0.1$ fb at Tevatron, not detectable, but may be possible at LHC (higher L and $\sigma = 1-10$ fb?)

LHC (2-3 years) $\sim 30/\text{fb}$

Theory can be tested, low x gluonic features of proton measured with exclusive $\gamma\gamma$, χ_c^0 and χ_b^0 production.

u-loop : $\gamma\gamma$	c-loop : χ_c^0
b-loop : χ_b^0	t-loop : H

Hadrons with same quantum numbers as Higgs.

Central Exclusive Production of Higgs

Higgs has vacuum quantum numbers, vacuum has Higgs field.

So $pp \rightarrow p+H+p$ is possible *in principle*.

Allowed states: $I J^{PC} = 0 \text{ even}^{++}$

$J \geq 2$ strongly suppressed at small p angle (t)

If measure p's:

4-vectors

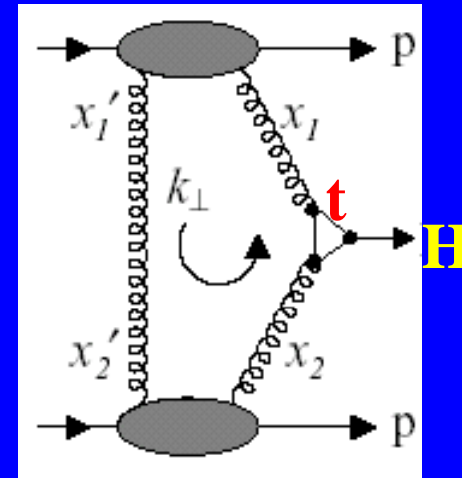

$$M_{\text{CEN}} = \sqrt{(p_1 + p_2 - p_3 - p_4)^2} \longrightarrow \sigma(M_H) \approx 2 \text{ GeV per event}$$

MGA+Rostovtsev: hep-ph/0009336

Even for $H \rightarrow W^+W^- \rightarrow l^\pm \nu JJ$!

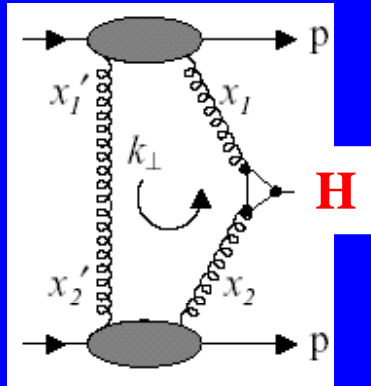

Aim: be limited by incoming beam momentum spread
{& can even that be reduced?}

$$\frac{\sigma_p}{p} \approx 10^{-4} = 0.7 \text{ GeV}$$

What is exclusive H cross section?

$$\sigma[pp \rightarrow p + H + p](M_H), \sqrt{s} = 14 \text{ TeV}$$

Calculation involves:

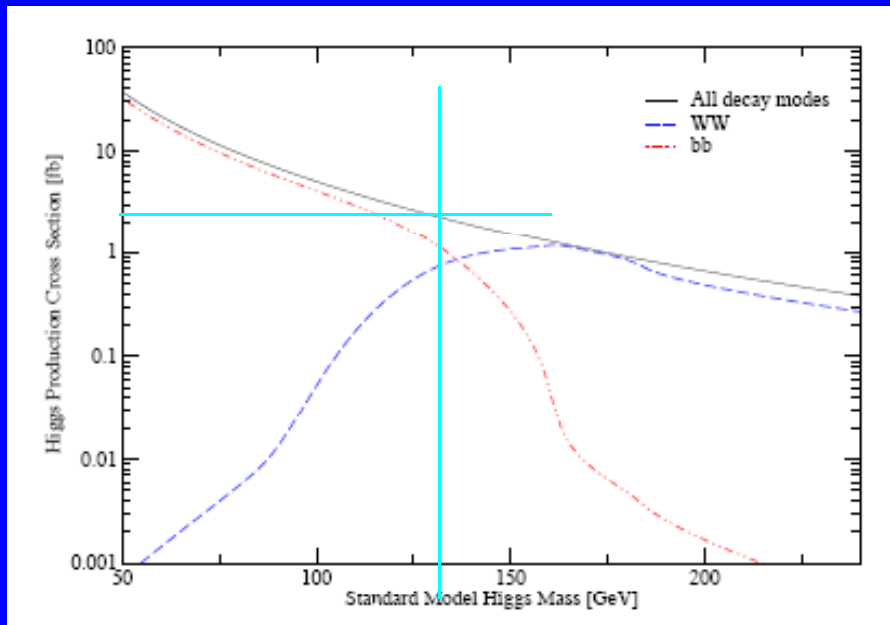

$gg \rightarrow H$ (perturbative, standard, NLO)

Unintegrated gluon densities $g(x_i).g(x_i')$

Prob.(no other parton interaction) (“Gap survival”)

Proton form factor

Prob.(no gluon radiation \rightarrow no hadrons) **Sudakov Suppression**

$\sigma \sim 3 \text{ fb}$ ($M(H)=130 \text{ GeV}$)
“factor ~ 3 uncertainty”

$\rightarrow 33 \text{ fb}^{-1} \rightarrow 100 \text{ Ae events}$
(Ae = acceptance, efficiency)

But other estimates differ
by “large” amounts!

Need to calibrate theory!

Durham Gp: Khoze, Martin, Ryskin, Stirling
hep-ph/0505240 ++

Exclusive Theory Calibration: Exclusive 2-Photon

MGA et al. (2001) hep-ex/0511057

Khoze, Martin and Ryskin, hep-ph/0111078, Eur.Phys.J. C23: 311 (2002)

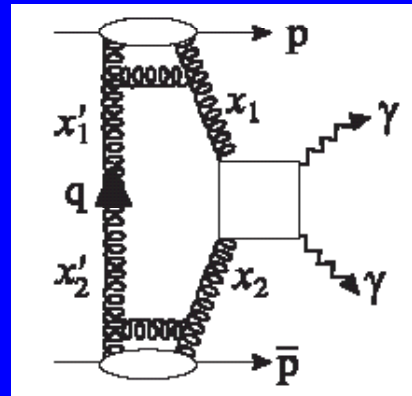

KMR+Stirling hep-ph/0409037

QCD diagram identical to pHp

$M(\gamma) \sim 10 - 20 \text{ GeV}$

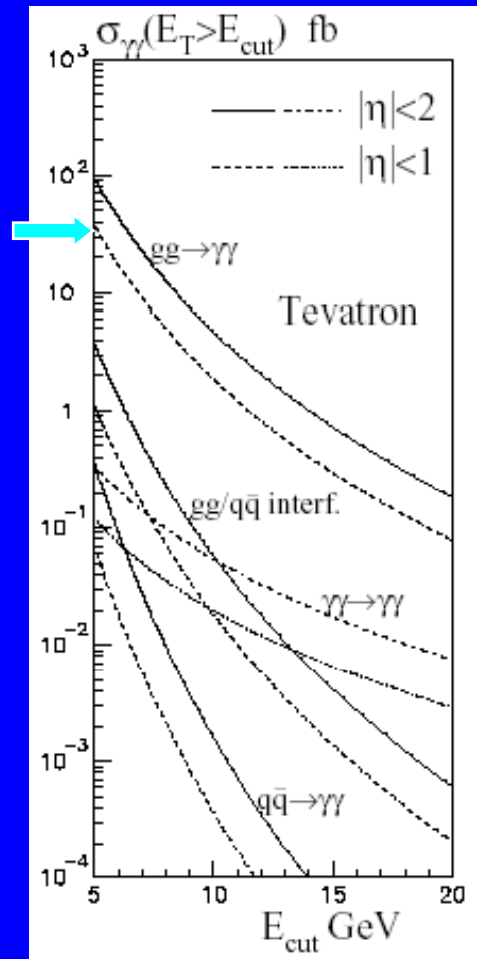

x_1, x_2 similar, Q^2 lower

top $\rightarrow u, c$ (mainly)

38 fb

Tevatron

$\sim 40 \text{ events per fb}^{-1}$ with $p_T(\gamma) > 5 \text{ GeV}/c$ & $|\eta| < 1.0$

Claim factor ~ 4 uncertainty ; Correlated to p+H+p

$\gamma\gamma \rightarrow \gamma\gamma$ & $q\bar{q} \rightarrow \gamma\gamma$ much smaller

Exclusive χ_c search: $p \bar{p} \rightarrow p \chi_c \bar{p}$

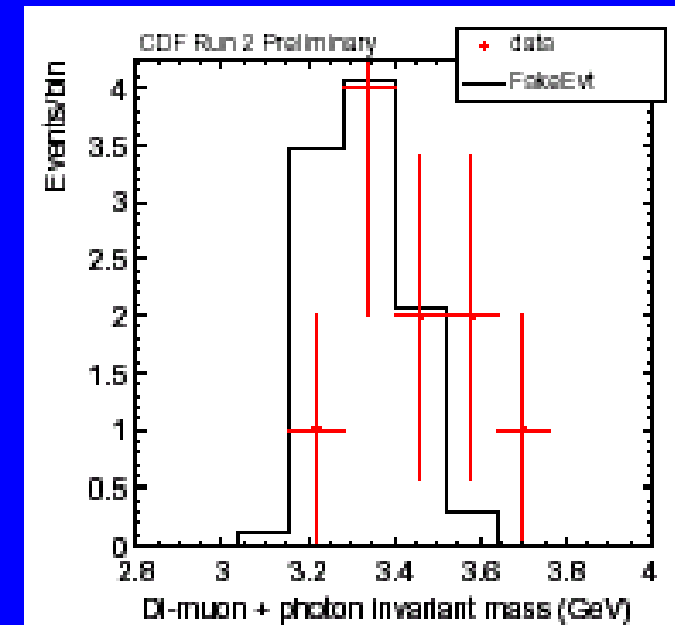

Predictions for Tevatron ~ 600 nb (~ 20 Hz!)
Angela Wyatt study (but she left!)

In reality: $\text{BR}(\chi_c^0 \rightarrow J/\psi \gamma \rightarrow \mu^+ \mu^- \gamma)$
 \times no other interaction \times acceptance(trig)
 \Rightarrow few pb (1000's in 1 fb^{-1})

Difficulty is soft photons, and “background”
From photoproduction: $\gamma + IP \rightarrow J/\psi$

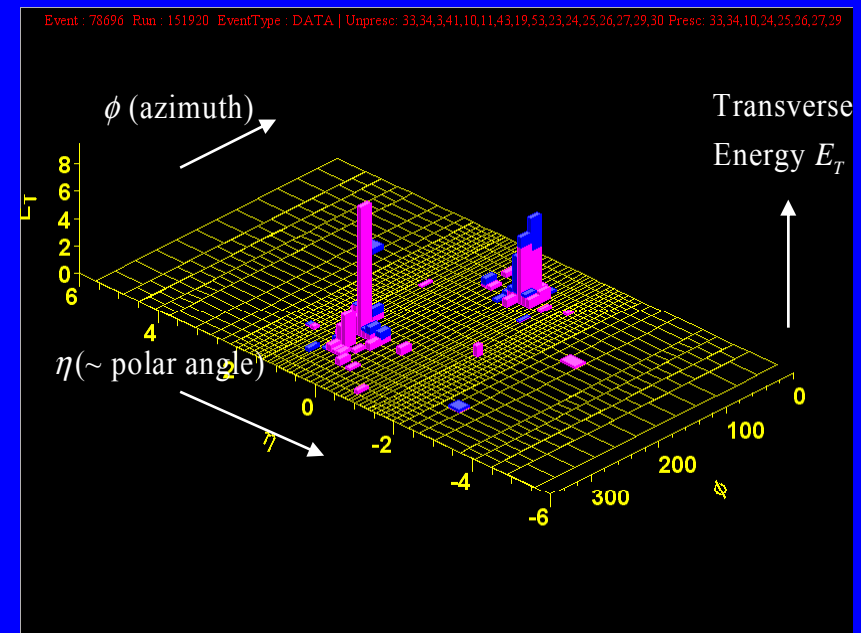

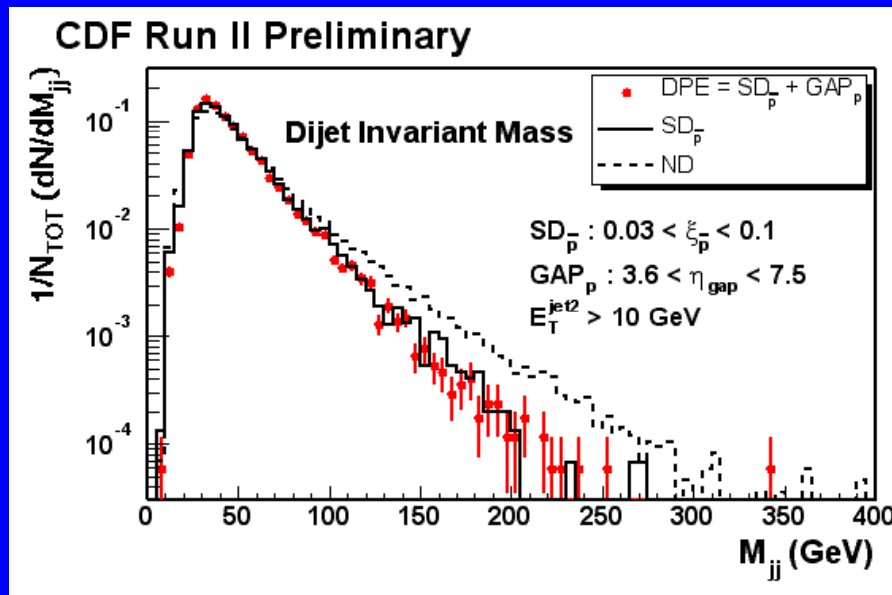

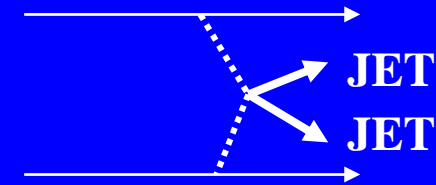

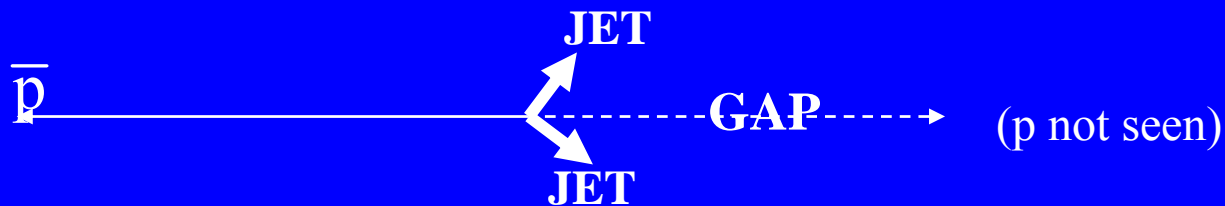

{Measuring forward $p \rightarrow$ central quantum numbers
 $2+$ forbidden at $t=0$ for $q\bar{q}$ state}

$I^G J^P = 0^+ 0^+ \leftarrow$ Isotopic spin, spin, G-parity, parity same as Higgs boson

Candidate events

Double Diffractive Di-Jets in CDF

Jet $\langle E_T \rangle$ spectra \sim same in SD and DPE

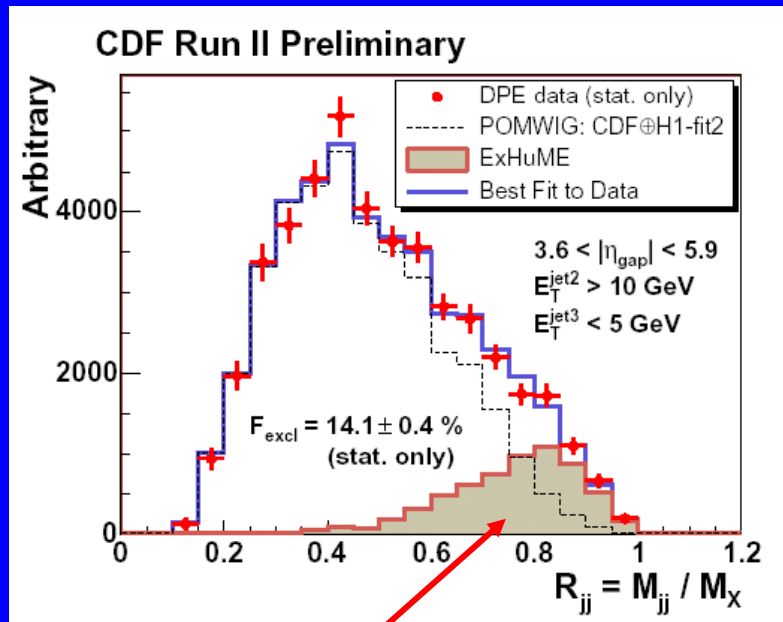

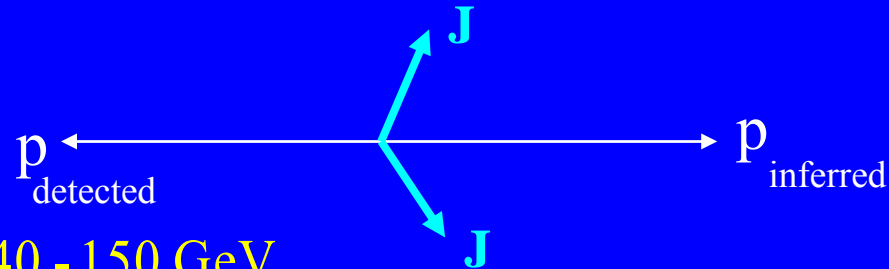

“Almost” exclusive di-jet,
Two jets and nothing else

$$\frac{M_{JJ}}{M_{CEN}} > 0.8$$

CDF Search for Exclusive Dijets (2 central jets + “nothing”)

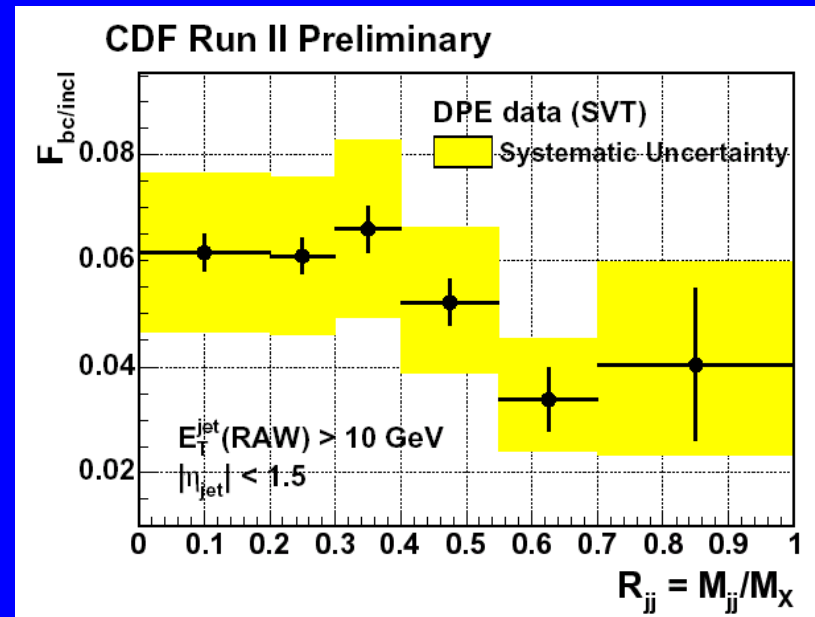

$$R_{JJ} = \frac{M_{JJ}}{M_X} \approx 1.0$$

M_X = total central mass $M_{JJ} \approx 40 - 150$ GeV

ExHuME: MC with
exclusive di-jets.

Cross section comparison not yet done

Apparent b-jet suppression
as they become exclusive ?
 (Theoretically $\rightarrow 0$ as $R_{jj} \rightarrow 1$, $J_z=0$ rule)
 Greatly reduces QCD background

Exclusive 2-photon Search in CDF

$$p\bar{p} \rightarrow p + \gamma\gamma + \bar{p}$$

Cannot detect protons. Need to look for $\gamma\gamma$ + nothing.

Trigger on 2 EM4 showers + forward BSC1 veto. ($5.4 < |\eta| < 5.9$)

Require all calorimetry and Beam Shower Counters ($-7.4 < \eta < +7.4$)
in pedestals except 2 EM showers > 5 GeV. (1.2 mrad)

Can only use events with no other collisions in bunch crossing.

→ “exclusive efficiency” = 0.086

$\sim 2.10^6$ triggers in 532 pb^{-1} delivered, $L_{\text{effective}(\text{si})} = 46 \text{ pb}^{-1}$

19 events have 2 EM showers with

$E_T > 5 \text{ GeV}$ and $|\eta| < 2.0$ + nothing else

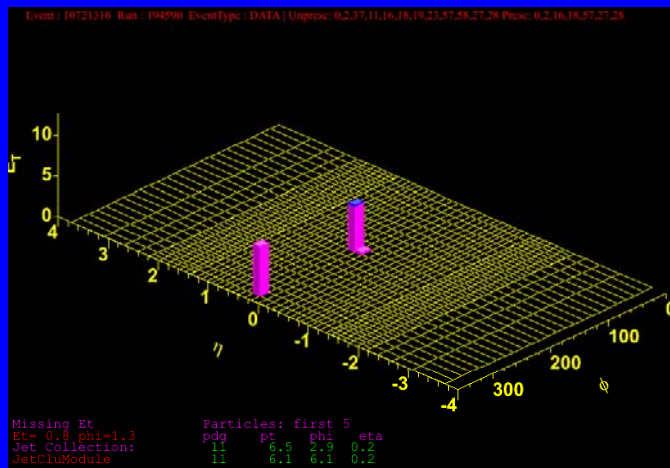

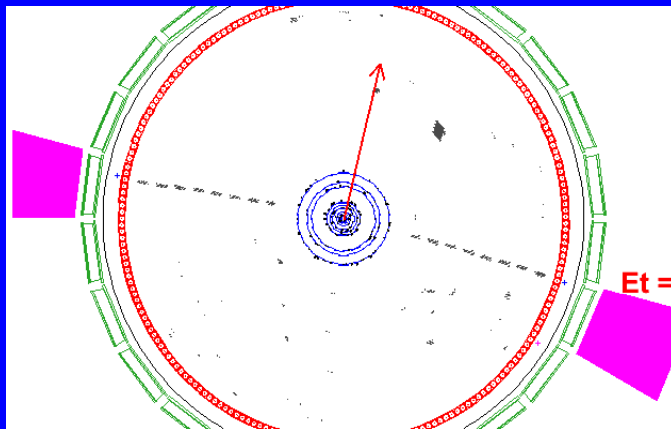

No track requirements yet ...

16 events were like this:

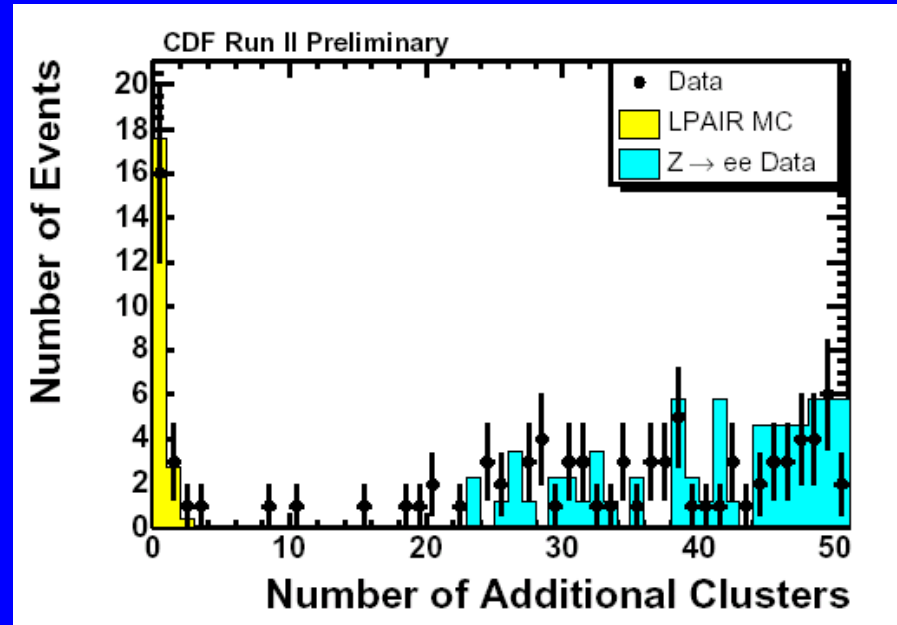

$$e^+e^- : \quad \Delta\phi = 180^\circ \pm 2^\circ$$

$$M(e^+e^-)_{10} \rightarrow 38 \text{ GeV}$$

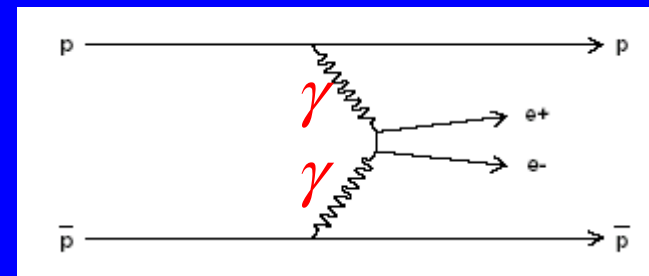

Δp_T small (\cong resolution)

Different fits \rightarrow “exclusivity background” under 0 peak 0.3 ± 0.1

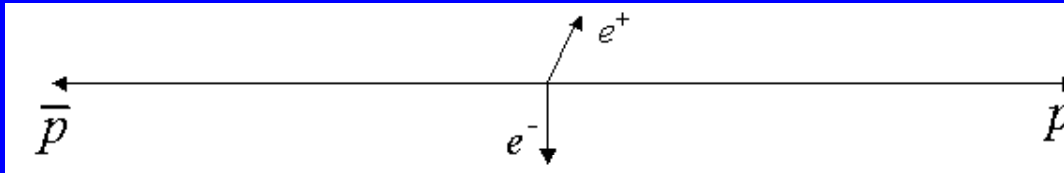

QED process : $\gamma\gamma$ collisions!

Monte Carlos : LPAIR, GRAPE

Observation of Exclusive Electron-Positron Production in Hadron-Hadron Collisions

PRL 98, 112001 (2007)
hep-ex/0611040

16 events observed $E_T(e^\pm) > 5 \text{ GeV}; |\eta(e^\pm)| < 2.0$

Estimated background = 1.9 ± 0.3

(mostly p-dissociation) \Leftrightarrow all products $|\eta| > 7.4$

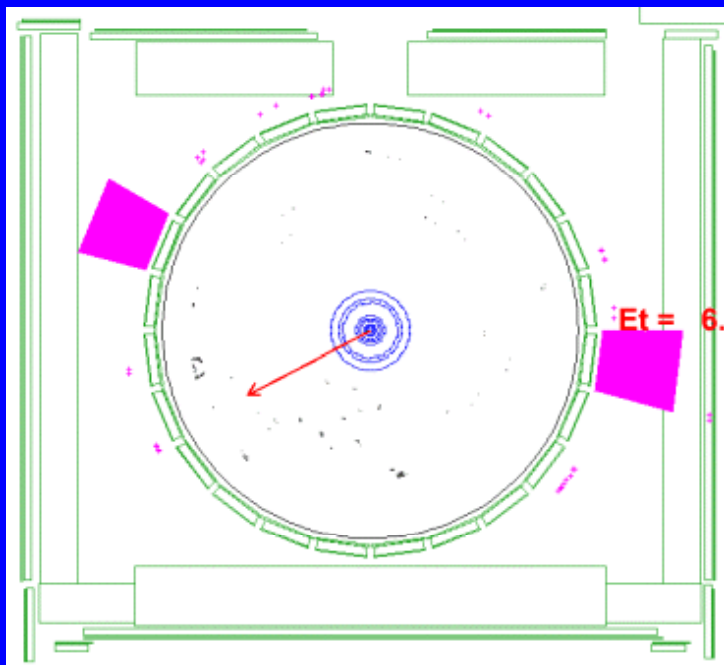

$\sigma_{MEAS.} = 1.6^{+0.5}_{-0.3} \text{ (stat)} \pm 0.3 \text{ (syst) pb}$ $\leftarrow y_{beam} = 7.65$

p-value = $1.3 \times 10^{-9} (\equiv 5.5\sigma)$

QED: LPAIR Monte Carlo: $\sigma_{QED} = (1.711 \pm 0.008) \text{ pb}$ \leftarrow

(Excellent agreement gives confidence in technique)

3 events were like this:

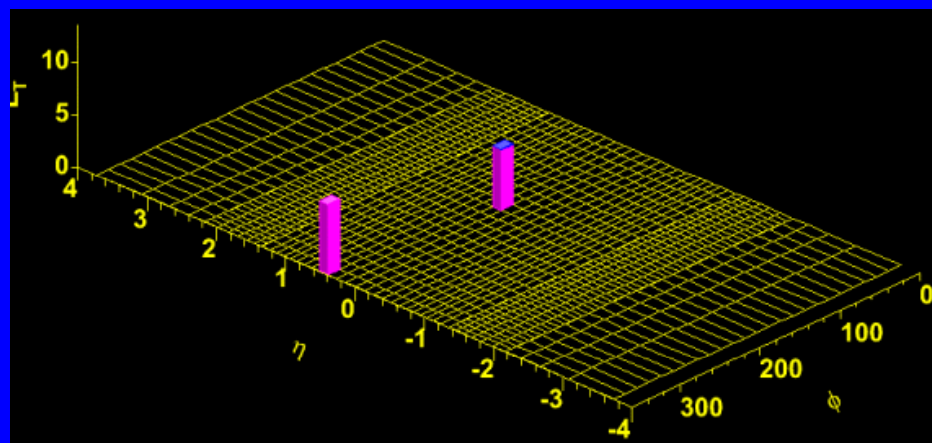

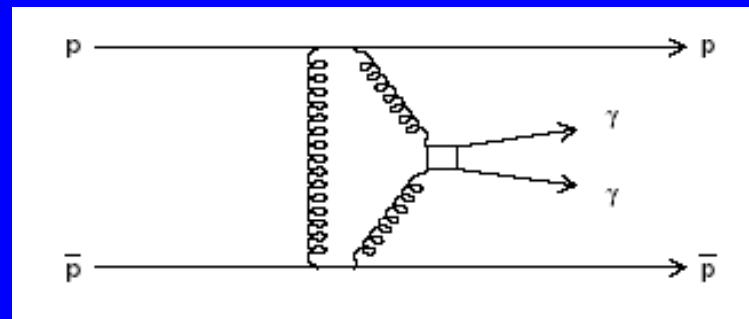

$$\gamma\gamma / \pi^0\pi^0 : \quad \Delta\phi > 175^\circ$$

$$M(\gamma\gamma / \pi^0\pi^0) 10 \rightarrow 12 \text{ GeV}$$

ΔE_T small

QCD + QED process

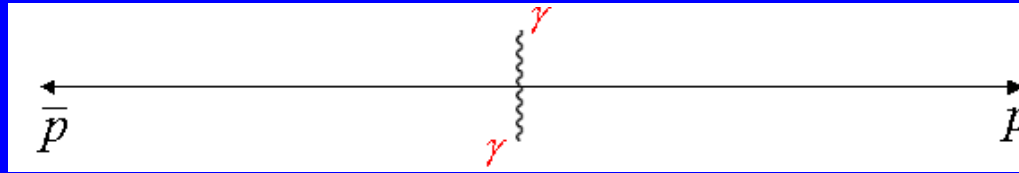

$$gg \rightarrow \gamma\gamma$$

ExHuME Monte Carlo
James Monk &
Andy Pilkington (MCR)

Exclusive $\gamma\gamma$ Production in Hadron-Hadron Collisions

Draft with CDF

Exclusive $\gamma\gamma$ pairs

3 candidates observed $E_T(\gamma) > 5 \text{ GeV}; |\eta(\gamma)| < 1.0$

Actually 2 events are good $\gamma\gamma$ candidates
and 1 is a good $\pi^0\pi^0$ candidate.
(Remember $\pi^+\pi^-$ at ISR)

Results just “blessed” by CDF

Can the 3 candidates be exclusive $\pi^0\pi^0$ or $\eta\eta$ rather than $\gamma\gamma$?

$\gamma\pi, \gamma\eta$ are forbidden by C-parity

$\pi\eta$ is forbidden by isospin

Theory (Durham): $\pi^0\pi^0 / \gamma\gamma \approx 0.25$ and $\eta^0\eta^0 / \gamma\gamma \approx 1$

We will give an upper limit on the $\gamma\gamma$ cross section,
which is valid independent of the $\pi^0\pi^0$ and $\eta\eta$
background in the 3 candidates.

Note : $\sigma_{MEAS} \approx 2 \times 10^{-12} \sigma_{INEL}$!

Conclusion: We have observed:

3 candidates for exclusive $(\gamma\gamma + \pi^0\pi^0 + \eta\eta)$ production

May be mixture

$$B/G = 0.09 \pm 0.04; \quad P(\geq 3) = 1.7 \times 10^{-4} \equiv 3.7\sigma$$

$$\sigma(\gamma\gamma) < 410 \text{ fb (95\% c.l.)}$$

A, B favor $\gamma\gamma$ and C favors $\pi^0\pi^0$

If we assume that 2 of the 3 candidates are gamma-gamma events we obtain a cross section: $\sigma(2 \text{ events}) = (90_{-30}^{+120} \pm 16) \text{ fb}$

cf

Durham Group Khoze, Martin, Ryskin & Stirling
hep-ph/0507040 Eur.Phys.J C38 (2005) 475 :
40 fb with factor 3 uncertainty

Existence of exclusive $\gamma\gamma$ implies that exclusive H must exist (if H exists)

Agreement with Durham group suggests H cross section at LHC in reach

Central Exclusive $\mu^+ \mu^-$ Production

Why interesting?

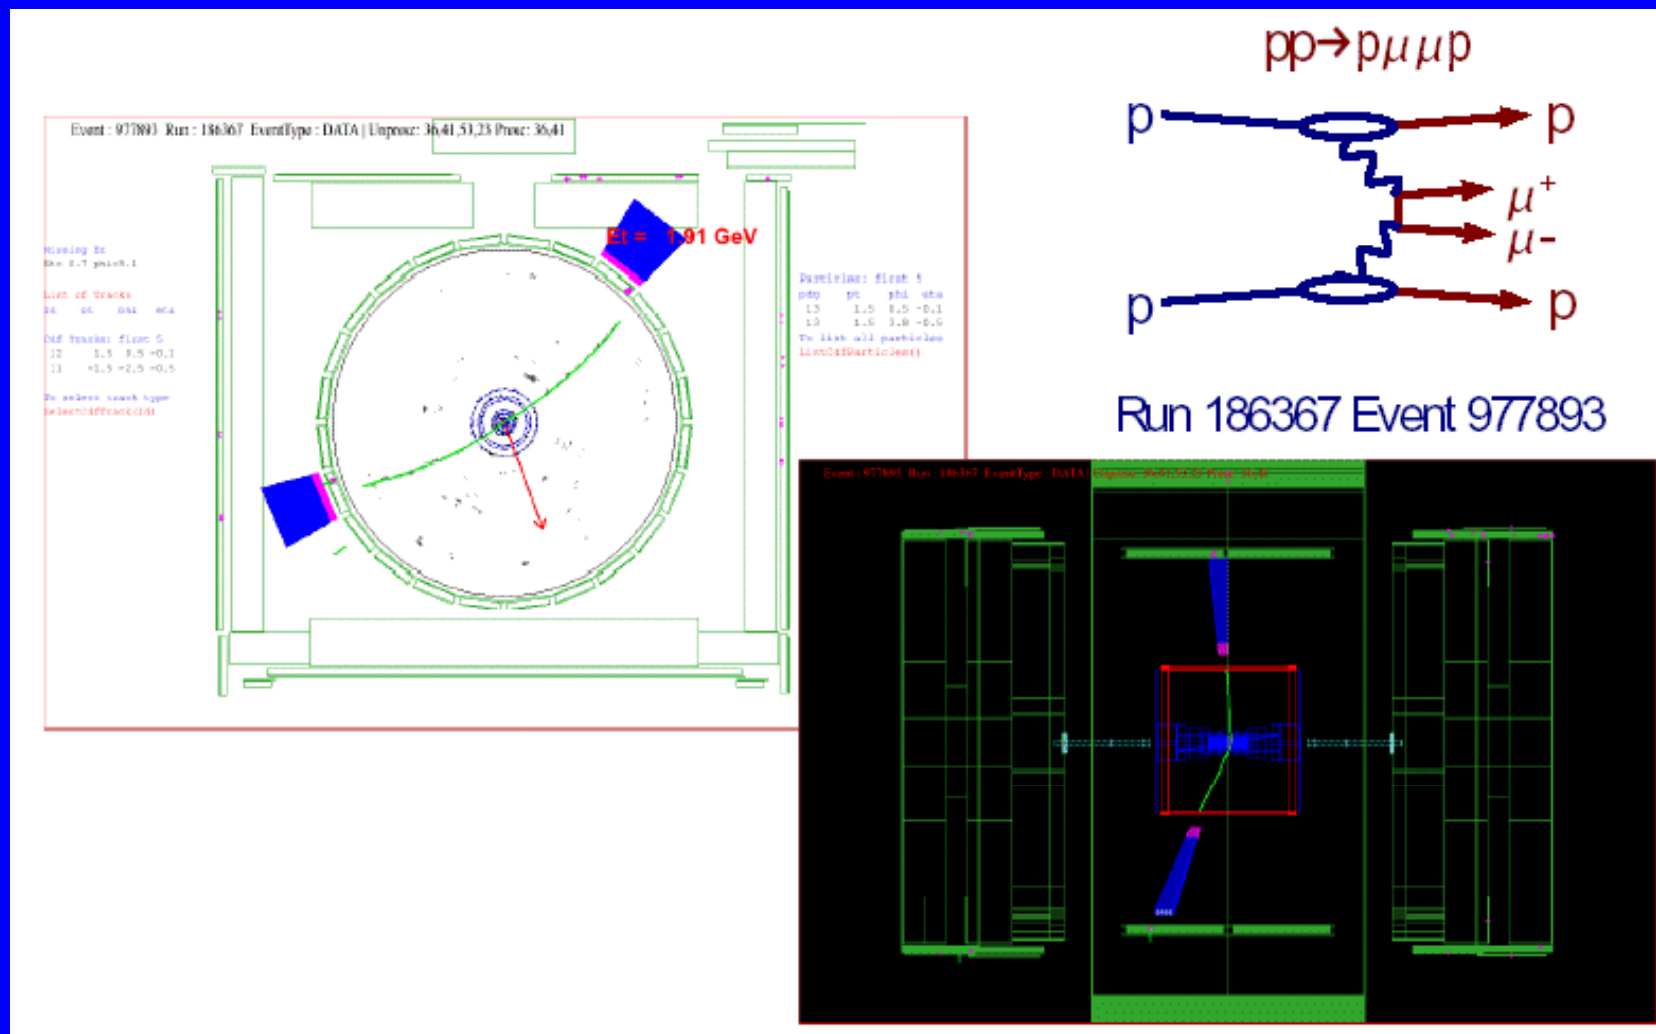

Among other things:

Two-photon production: $\gamma\gamma \rightarrow \mu^+ \mu^-$ continuum.

Cross section very well known (QED) so can calibrate LHC luminosity, if can do with pile-up.

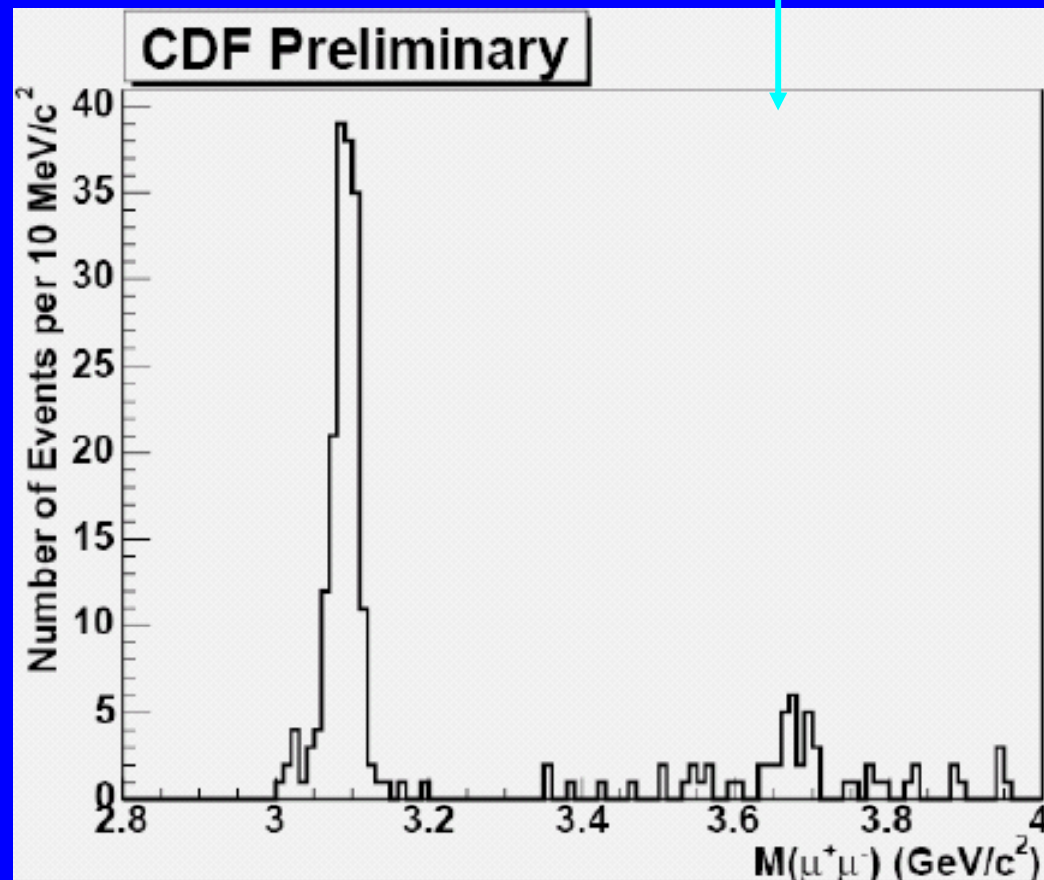

*Forward proton momenta precisely known:
calibrate momentum scale of forward spectrometers.*

We installed a trigger: μ^+ track + forward gaps (BSC1)
 Being studied. Have candidates:

Preliminary spectrum: Exclusive di-muon candidates

J/psi : photoproduction
(1st time in hadron-hadron) **psi(2S)(3686)**

Continuum (2-photon)

Acceptance rising strongly through M-range

Search for exclusive $\mu^+ \mu^-$ in presence of pile-up.

Potential use as luminosity calibrator. (But can be done with lowish luminosity.)

Inclusive di-muon trigger (no gap requirement, no pre-scales)

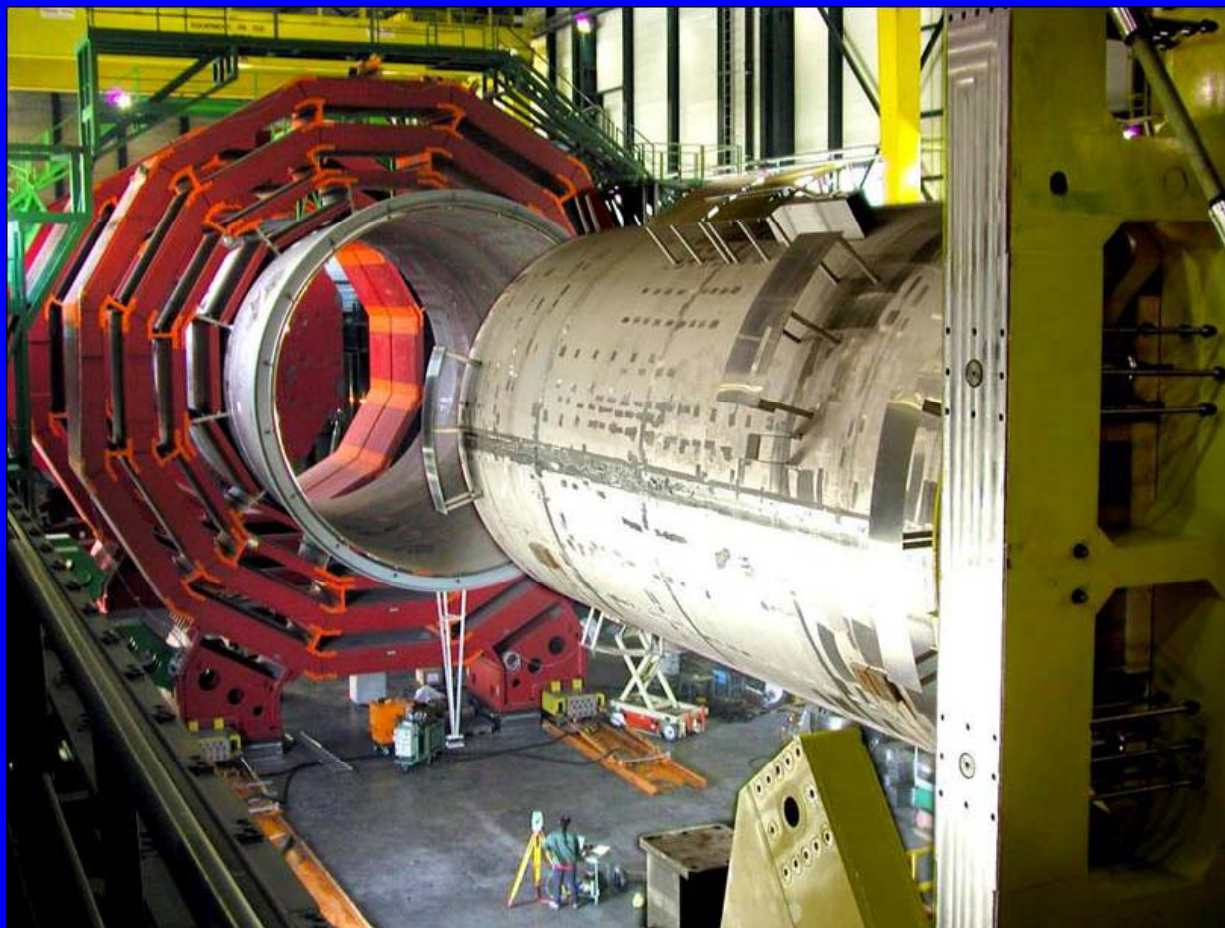

$$\begin{aligned} p_T(\mu^+) &= p_T(\mu^-) \\ \Delta\phi(\mu^+ \mu^-) &= 180^\circ \\ n_{\text{associated}}(\text{tracks}) &= 0 \end{aligned}$$

(because in 2-photon (Coulomb) process, p's have very small pT)

If see associated p (at LHC), know its momentum to $< 10^{-4}$
Calibrate forward proton spectrometers

FP420 : Forward Protons 420m downstream of CMS & ATLAS

Hopefully
both

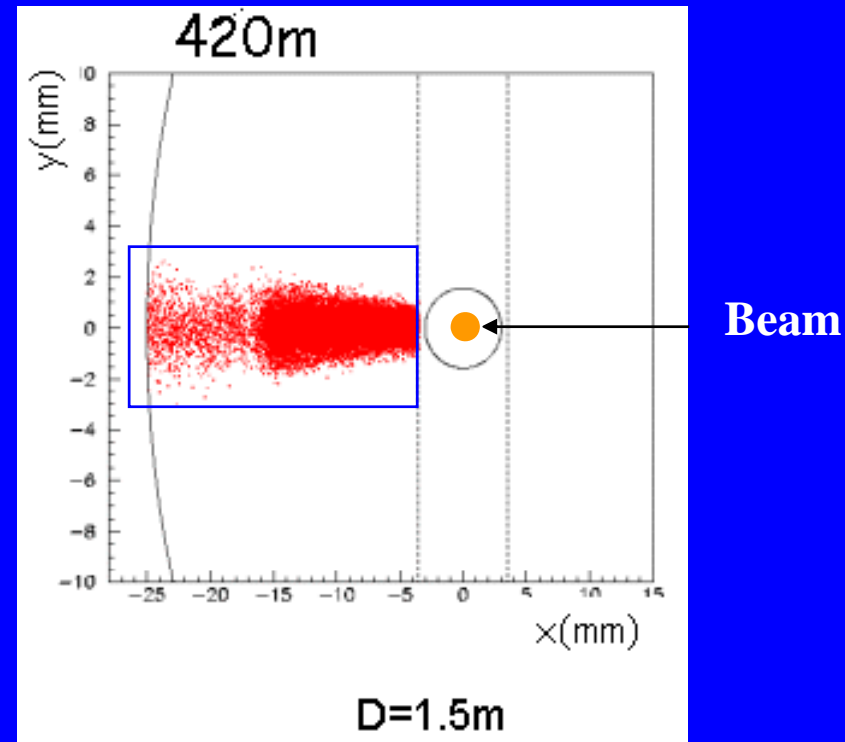

CMS: Inner Vacuum Tank insertion

Measure distance of track from beam (5-10 μm) and slope ($\sim 5\text{-}10 \mu\text{m}$ over 10 m) \rightarrow fractional momentum loss ξ

Protons, in x and y at detector
Generated flat in $\ln \xi, \ln x$
Normal Low- β operation

CERN Courier, Vol 43, Number 1, Jan 2003

$\sigma_{\text{TOF}}(z) \approx 4.2 \rightarrow 2.1 \text{ mm}$
cf $\sigma_z(\text{interactions}) \approx 52 \text{ mm}$

6mm(y) x 24mm (x)
covers distribution

Fast Timing Counters: GASTOFs and QUARTICs

Pile-Up background: p's, JJ or WW from different collisions

Counters with ~ 10 ps timing resolution behind tracking

$$10 \text{ ps} = 3 \text{ mm}$$

$$\frac{3\text{mm}}{\sqrt{2}} = 2.1\text{mm}$$

- 1) Check both p's from same collision (reduce background)
- 2) Get z(vertex) to match with central track vertex
- 3) Tell what part of bunches interacting protons were (F-M-B)

Likely solution:

Cerenkov light in gas or quartz (fused silica) bars →

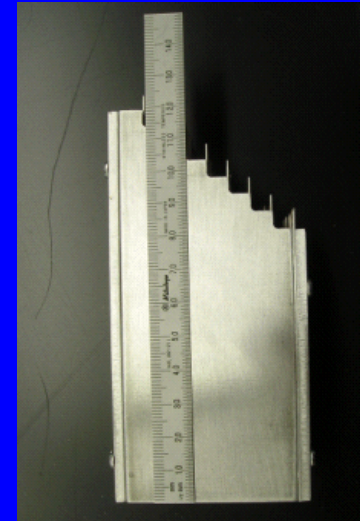

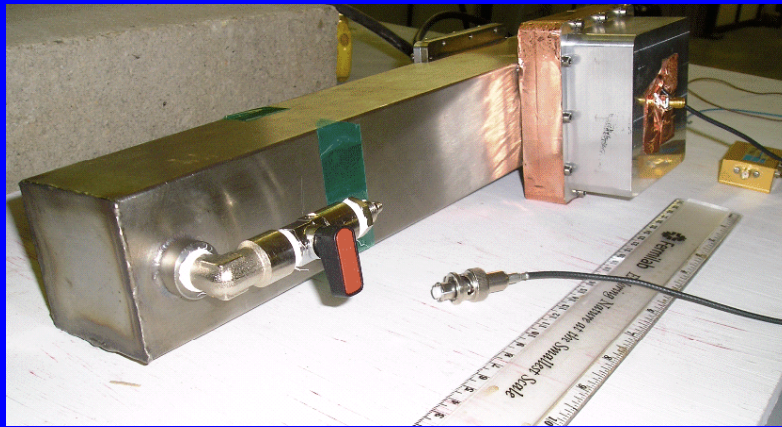

MCP-PMT (Micro-Channel Plate PMT) (or Si-PMT?)

Also possible (?): 3D-silicon optimised for timing

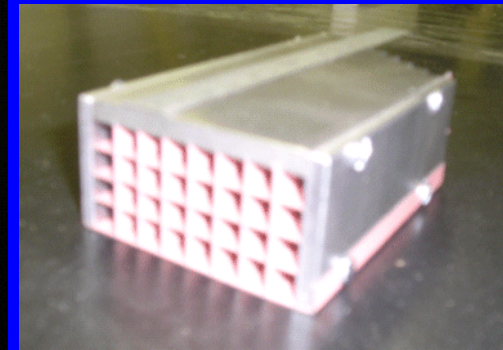

Precision Timing: Testing GASTOF and QUARTIC Prototypes

Had 1st round test beam studies at Fermilab. 2nd round Feb-March
Results not yet final... need good tracking for x,y corrections (2mm = 10um)

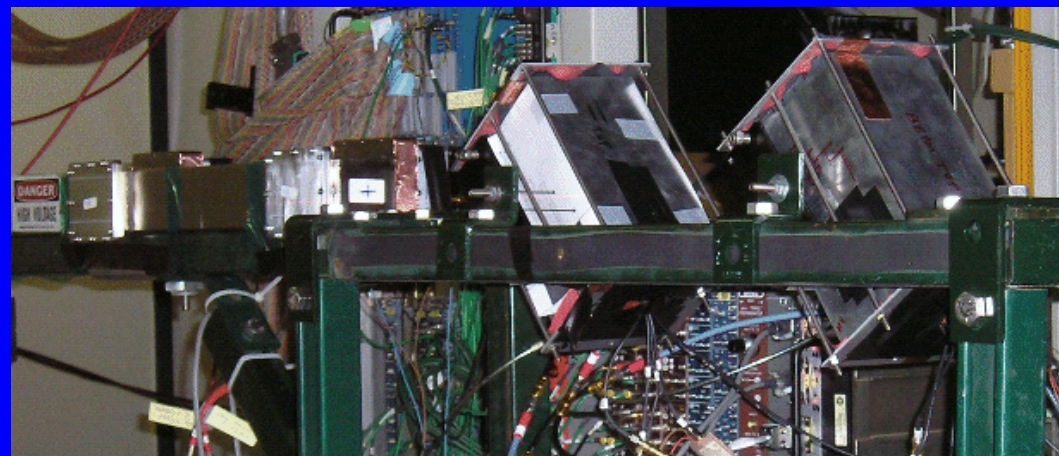

GASTOF (U.Louvain) ... real is smaller

QUARTIC2

Test beam setup

Exclusiveness brings many rewards. $H \rightarrow \text{Jet Jet}$ case

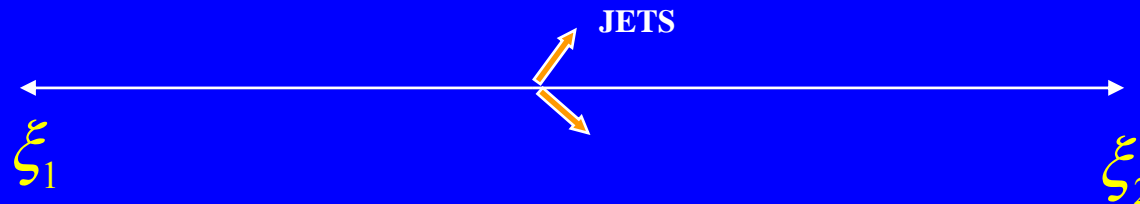

$$M_{\text{CEN}} = \sqrt{(p_1 + p_2 - p_3 - p_4)^2}$$

Two jets' E_T are the same to $\sim 1 \text{ GeV}$, $\Delta\phi=180^\circ$
 and, knowing that and η_1, η_2 and $\xi_1(220)$
 in L1 trigger (fast look-up) can use correlation
 to reduce L1 trigger rate.

$$\xi = 1 - \frac{p_z(\text{out})}{p_z(\text{beam})}$$

(fractional momentum loss)

$$\xi_{1(2)} = \frac{1}{\sqrt{s}} \sum_{\text{jets}} E_{Ti} e^{+(-)\eta_i}$$

420m just too far for L1 trigger. 420 + 220 + Jet info.

What is H Signal:Background? (not pile-up)

$H(120-135 \text{ GeV}) \rightarrow b\bar{b}$

Inclusively, $gg \rightarrow b\bar{b}$ background overwhelming

Exclusively, $pp \rightarrow p + qq + p$ ($q = \text{quark jet}$)

strongly suppressed at LO $\left(\sim \frac{M_q^2}{M_H^2} \right)$ by

spin selection rule $J_z = 0$.

Most "exclusive dijets" are gg

Need b-tagging, then $\frac{S}{B}(\text{SMH}) \sim 3 \times \frac{1 \text{ GeV}}{\sigma(M)}$

$q\bar{q}$ dijets strongly suppressed
 $J = 1$ forbidden, $J=0$ strongly favored
 $J = 0, 2$ discrimination possible

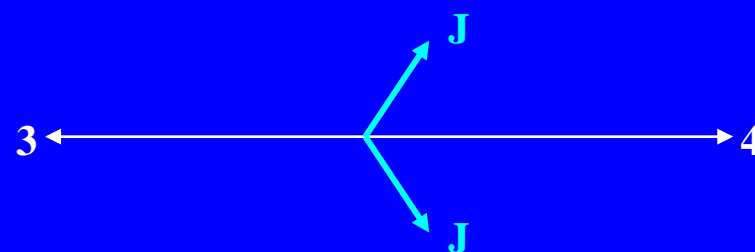

Trigger is issue:

Probably need asymmetric

220m + 420m and:

Eventual trigger upgrade??

$H \rightarrow b\bar{b}, W^+W^-, ZZ$

Kinematic constraints:

$$E_{T,1} \approx E_{T,2}; \quad \phi_1 = -\phi_2$$

$$\xi_{3(4)} = \frac{1}{\sqrt{s}} \sum_{1,2} E_T e^{-(+)\eta}$$

$$\left(\xi = 1 - \frac{p_{\text{out}}}{p_{\text{beam}}} \right)$$

What is Signal:Background? $H(135-200)$ (not pile-up)

$$H(135 - 200 \text{ GeV}) \rightarrow W^+ W^-$$

$$\sigma_{\text{incl}}(W^+ W^- \text{ non-}H) \sim 100 \text{ pb}; \sigma(H) \sim 20 \text{ pb}$$

& $M(WW)$ resolution v.poor ($\nu(s)$ and/or jets)

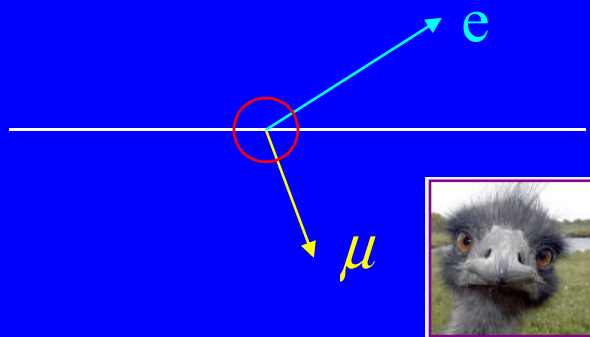

Exclusive B/G is $\gamma\gamma \rightarrow W^+ W^-$, $\sigma \sim 50 \text{ fb}$, continuum

Mass resolution $\sigma_M(WW^{(*)}) \sim 2 \text{ GeV}$ any decay

Exclusive $H \rightarrow ZZ$, negligible B/G

Examples: $WW \rightarrow l\nu l\nu$, $l = e, \mu$
NO OTHER TRACKS ON VERTEX!
(But only 4.6% of WW)

$$H(160) \rightarrow W^+ W^- \rightarrow p \ e^+ \mu^- \not{e}_T \ p$$
$$MM^2 = (p_1 + p_2 - p_3 - p_4)^2 = M_H^2$$

Always : $\sigma(M_{WW} \approx 2 \text{ GeV})!$

What is Signal:Background? $H(135-200) \rightarrow WW(*)$

$$WW \rightarrow l\nu JJ, l = e, \mu, \tau$$

Durham Gp: Khoze, Martin, Ryskin, Stirling hep-ph/0505240

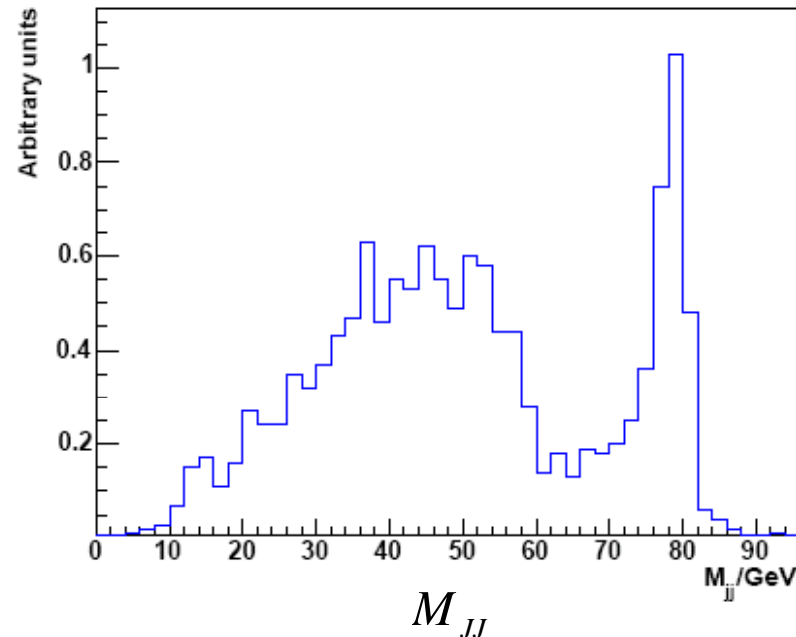

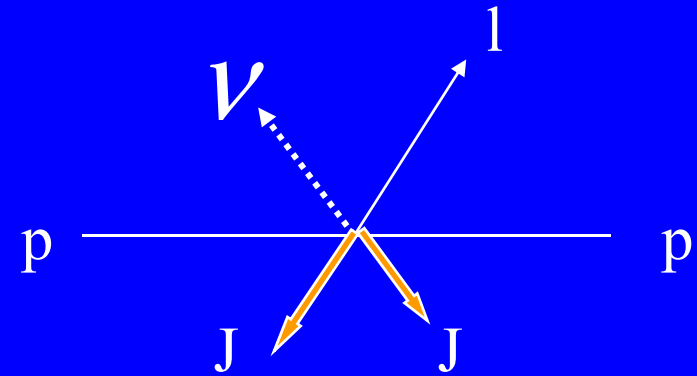

Fig. 6: The di-jet invariant mass distribution dN/dM_{JJ} in the semi-leptonic decay channel $H \rightarrow WW^* \rightarrow l\nu jj$ for $M_H = 140$ GeV.

$$MM(12-34JJl) \approx 0(M_\nu)$$

$$MM(12-34JJ) = M_W^{(*)} \text{ (even for } \tau\nu\text{)}$$

$$M(JJ) = M_W^{(*)}$$

**Can use ~ 50% of WW
(all but JJJJ)**

$$H(180) \rightarrow ZZ \rightarrow l^+ l^- \nu \bar{\nu} \text{ (BR } \sim 10 \times l^+ l^- l^+ l^-)$$

$$MM(12-34l^+ l^-) = M(Z_{\nu\bar{\nu}}), \sigma_M \sim 2 \text{ GeV!}$$

**!! Unfortunately
very few events (SM)**

In WW/ZZ case, central trigger effective (420+420 OK)

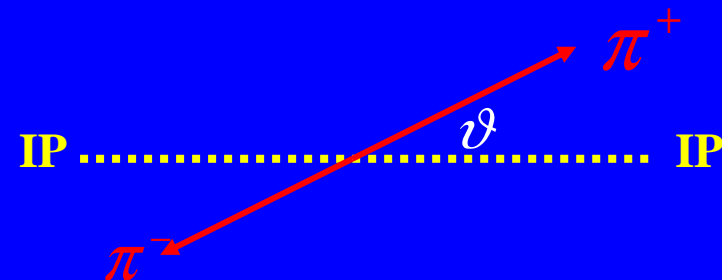

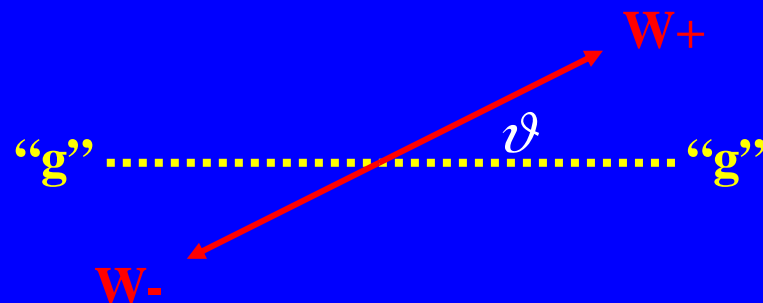

Determining Quantum Numbers of Central State (H?)

Is it $J = 0$, $CP = ++$?

In $gg \rightarrow X$ only $CP = ++$ is allowed.
(a CP -ve A (MSSM) is highly suppressed)

$gg \rightarrow$ vector ($J = 1$) forbidden, Yang's theorem.

$J = 0, 2$ can be distinguished by angular distributions
 \rightarrow partial wave analysis. Can even see states hidden in overall M distribution!

Moments $H(LM)$ of the $\cos(\vartheta)$ distributions $\rightarrow M(J=0), M(J=2)$.

e.g. ISR/R807 glueball search in $pp \rightarrow p + \pi^+ \pi^- + p$ NPB264 (1986) 154

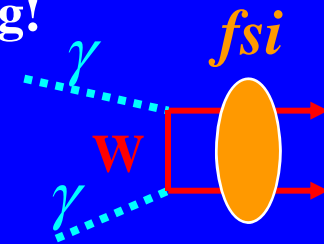

Non-SM cases : no Higgs? MSSM Higgses?

1) **No SMH?** Can we exclude? Suppose measure 100 exclusive $\gamma\gamma$ in CMS.
 (~ 0.1 fb⁻¹ effective S.I.Lum) → predict **p+SMH+p to ~ 20%**
 Expect (say) 100 pHp events in 30 fb⁻¹, see < 50. Conclusion?

2) No SMH or MSSM-Hs? WW physics becomes very interesting!

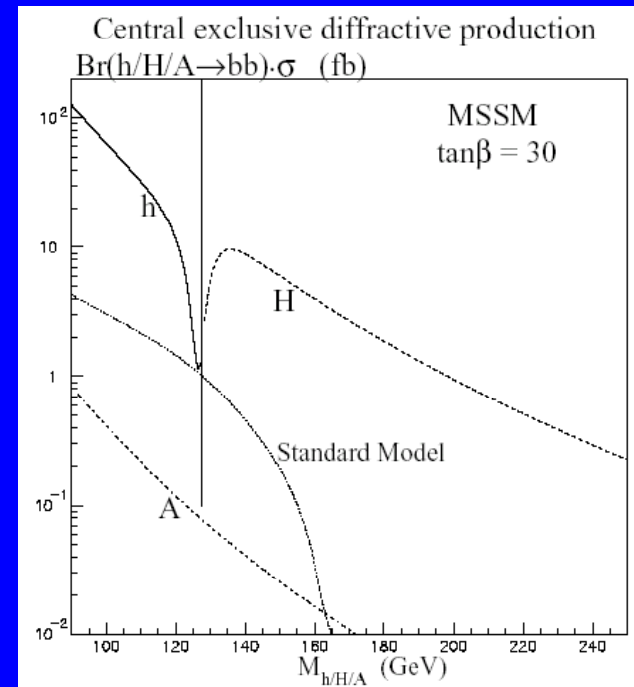

$pp \rightarrow p + W^+W^- + p$ via $\gamma\gamma \rightarrow W^+W^-$ $\sigma \approx 50\text{fb}$ (precisely known in SM)

W^+W^- Final State Interactions distort $\frac{d\sigma}{dM_{WW}}$, visibly? New physics?

Preview of ILC physics!

3) In case of SUSY, Forward p-tagging can be crucial! Cross section can be much higher than SMH. Decays to $b\bar{b}$ enhanced. $A(\text{CP -ve})$ highly suppressed.

Kaidalov Khoze Martin Ryskin
 hep-ph/0307064

MSSM

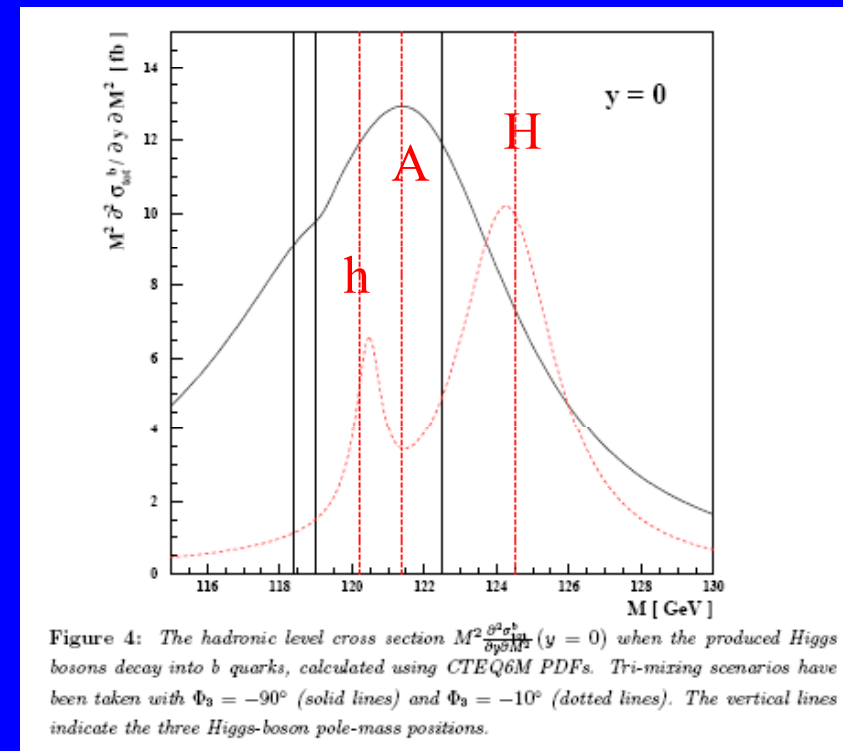

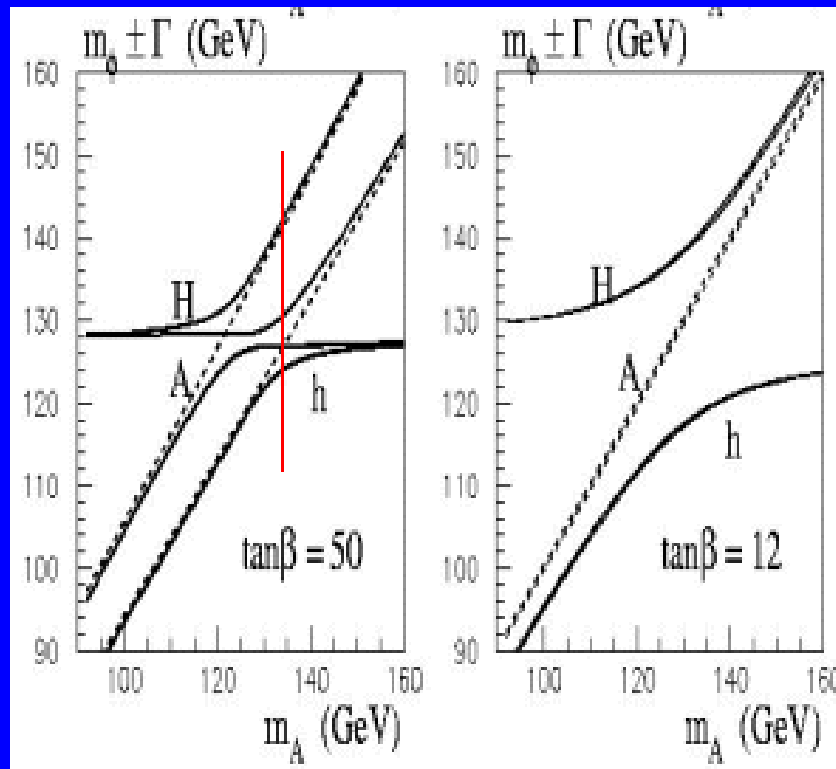

Can have $\{h, A, H\}$ close together in mass (few GeV)

Hard to resolve by inclusive production.

Exclusive advantages: higher production than SM, A highly suppressed

Excellent mass resolution could separate h and H (unique)

Excellent mass resolution might even measure H widths (if \sim few GeV)

Durham Group (KMRS)

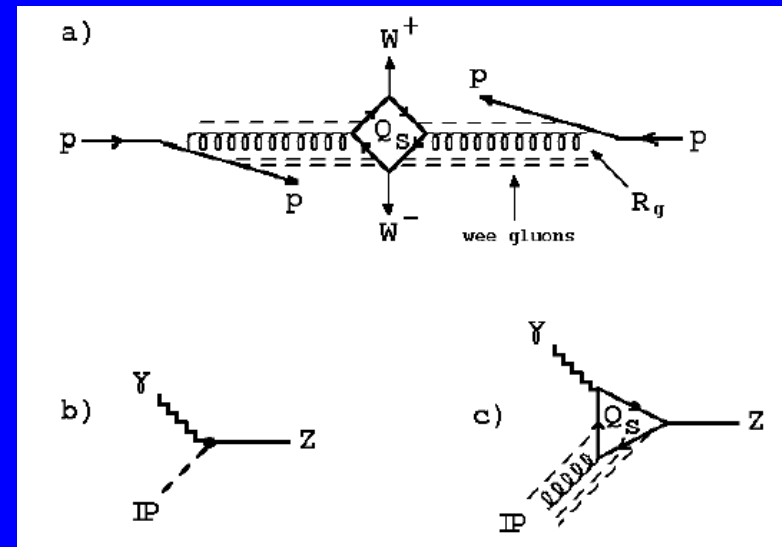

J.Ellis, J.S.Lee and A.Pilaftsis, PRD71:075007, hep-ph/0502251

BSM: The White Pomeron

Alan White (ANL)

BFKL Pomeron = 2 reggeized gluons / ladder
White Pomeron = 1 reggeized gluon + sea wee g's

Asymptotic freedom \rightarrow 16 color triplet q's
Only 6 known (d u s c b t)
But (!) 1 color sextet Q counts 5 times, so
 $\{ud\} + \{cs\} + \{tb\} + \{UD\}$ works!

$\Pi = U\bar{D}$ etc, η_6 ...EWSB, role of Higgs “*composite higgs*”

Can be dark matter ($N = DDU \sim \text{TeV}$)

Pomeron couples strongly to WW through U,D loops

\rightarrow Anomalous (quasi-diffractive) production of WW, ZZ
(not WZ) production at LHC ($M(\text{DPE@LHC}) < \sim 700 \text{ GeV}$).
Also Z photo-production possible at LHC

Dramatic effects at LHC, especially in $pp \rightarrow p + WW/ZZ + p$

Status of FP420 R&D Project

LOI to LHCC July 2006

Plan on TDR → LHCC, CMS, ATLAS

~ May 2007. Install in 2009-2010.

<http://www.fp420.com/>

1 Executive Summary

2 Introduction to the FP420 R&D Collaboration

3 Introduction to Central Exclusive Processes

- 3.1 Advantages of central exclusive production.....
 - 3.1.1 Missing mass measurement.....
 - 3.1.2 Quantum number filtering and determination.....
 - 3.1.3 Background suppression, $J_Z = 0$ rule.....
 - 3.1.4 Other kinematic constraints.....
- 3.2 Exclusive production of a Standard Model Higgs boson.....
- 3.3 Exclusive production of a Supersymmetric Higgs bosons.....
- 3.4 Related exclusive processes.....
 - 3.4.1 χ_s and χ_b , J/ψ and Υ
 - 3.4.2 $\gamma\gamma$ and $\pi^0\pi^0$
 - 3.4.3 Jet-Jet and B di-jets.....

4 Two-Photon and Related Processes

- 4.1 Two-photon processes at LEP, HERA and Tevatron.....
- 4.2 Exclusive lepton pair production at LHC.....
 - 4.2.1 e^+e^- cross sections and kinematics, triggering.....
 - 4.2.2 $\mu^+\mu^-$ cross sections and kinematics, triggering.....
 - 4.2.3 $\tau^+\tau^-$ cross sections and kinematics, triggering.....
- 4.3 W^+W^- production in two-photon interactions.....
 - 4.3.1 Standard Model case.....
 - 4.3.2 Beyond the Standard Model case.....
- 4.4 Photoproduction.....
 - 4.4.1 $\gamma p p \rightarrow J/\psi, Y, Z(?)$

5 Proton Optics and Machine Constraints

- 5.1 The detector station at 220m.....
 - 5.1.1 Beam halo and radiation levels at 220m.....
- 5.2 The proposed detector station at 420m.....
- 5.3 The cryogenic by-pass.....
- 5.4 Measuring proton momenta through the lattice.....
- 5.5 Transfer matrices.....
- 5.6 Simulations of leading protons.....
- 5.7 Resolutions in momentum (and ξ, t and missing mass).....

6 Backgrounds

- 6.1 Irreducible "single interaction" background.....
- 6.2 Luminosity dependent pile-up background.....
- 6.3 Background from beam halo and upstream interactions.....
- 6.4 Background reduction techniques.....

7 The Detector Stations at 420m.

- 7.0.1 Beam halo and radiation levels at 420m.....
- 7.1 The moving pipe design.....
 - 7.1.1 Precision mechanics and motion control.....
- 7.2 Tracking specifications.....
- 7.3 3-D silicon detectors.....
 - 7.3.1 Performance in beam tests.....
 - 7.3.2 Radiation Hardness.....
 - 7.3.3 Alignment.....
 - 7.3.4 Cooling.....
- 7.4 Beam position monitors.....
- 7.5 Fast Timing.....
 - 7.5.1 Timing Specifications.....

- 7.5.2 GASTOFs: Gas Time of Flight detectors.....
- 7.5.3 QUARTICs: QUARtz Timing Counters.....
- 7.5.4 Performance in beam tests.....

- 7.6 Interface to LHC issues.....

8 Full Event Simulations

- 8.1 Event generators.....
- 8.2 ATLAS detector simulation.....
- 8.3 CMS detector simulation.....

9 Data Acquisition and Triggering

- 9.1 Tracking detector local electronics.....
- 9.2 Timing detector local electronics.....
- 9.3 Slow controls and monitoring.....
 - 9.3.1 Low Voltages.....
 - 9.3.2 High Voltages.....
 - 9.3.3 Temperatures.....
 - 9.3.4 Positions.....
- 9.4 Local-Central communication.....
 - 9.4.1 Optical fiber communication.....
 - 9.4.2 Cables and Infrastructure in tunnel.....

- 9.5 Central DAQ.....
 - 9.5.1 ATLAS-Spec.....
 - 9.5.2 CMS-Specifi.....
- 9.6 Level 1 Trigger.....
 - 9.6.1 ATLAS-Spec.....
 - 9.6.2 CMS-Specifi.....
- 9.7 High Level Trigger.....

- 9.7.1 ATLAS-Specific high level trigger.....
- 9.7.2 CMS-Specific high level trigger.....

10 Detectors at 220m

- 10.1 New 220m detectors in CMS.....
- 10.2 New 220m detectors in ATLAS.....

11 Reconstruction and Off-Line Analysis

12 Cost and Budgets

- 12.1 Cryogenic by-pass and mechanics.....
- 12.2 Detectors.....
 - 12.2.1 Tracking.....
 - 12.2.2 Timing.....
- 12.3 Electronics.....
- 12.4 Other Costs.....

13 Time-Line

- 13.1 Further R&D planned.....
- 13.2 Installation Issues, and requests to CERN.....

14 Request to ATLAS, CMS and LHCC

15 Acknowledgements

New collaborators welcome!

Detectors: timing, tracking, BPMs, DAQ, Triggering. Simulations, pre-analysis...

Exclusive Central Production in Proton Proton Collisions

Small-x March 2007

Summary

Any states with **vacuum quantum numbers** and strong or electromagnetic couplings can be produced at LHC by

Central Exclusive Production

This includes Higgs boson(s), W-pairs, lepton and photon pairs.

Cross section $pp \rightarrow p+SMH+p$ known to factor ~ 3 (~ 3 fb) (?)

If protons well measured, can get mass of central state to
 ~ 2 GeV per event, **Quantum numbers (J, CP)** and couplings to gg.

S:B can be good – **excellent in BSM scenarios.**

For good acceptance/resolution need both 220m and 420m detectors.

R&D on FP420: tiny but v.high precision tracking, timing, BPM

Best particle spectrometer ever, using part of LHC

We aim to propose this as upgrade to CMS (and ATLAS) in 2007

for installation in 2009-2010

PS \rightarrow
