

ATLAS in a nutshell

Visite ACTIF (Association CEA des Thésards d'Ile de France), June 14th

Fabrice Balli, Henri Bachacou

The Standard Model (SM)

Standard Model of Elementary Particles

	three generations of matter (fermions)			interactions / force carriers (bosons)	
	I	II	III		
mass	=2.2 MeV/c ²	=1.28 GeV/c ²	=173.1 GeV/c ²	0	=125.11 GeV/c ²
charge	2/3	2/3	2/3	0	0
spin	1/2	1/2	1/2	1	0
	u up	c charm	t top	g gluon	H higgs
	d down	s strange	b bottom	γ photon	
	e electron	μ muon	τ tau	Z Z boson	
	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	W W boson	

QUARKS (left side of the table)

LEPTONS (left side of the table)

GAUGE BOSONS VECTOR BOSONS (right side of the table)

SCALAR BOSONS (right side of the table)

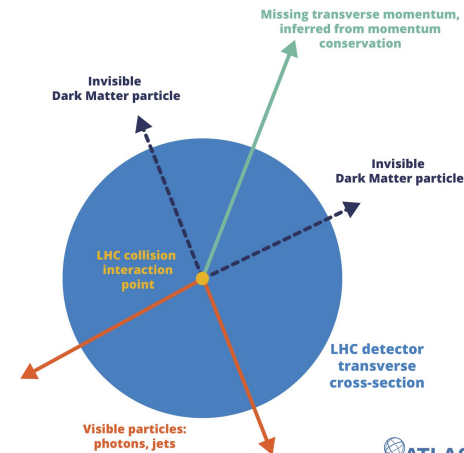

- Basic model of fundamental constituents of matter
 - Developed in 2nd half of 20th century
 - Builds on Quantum Field Theory
 - Quarks, leptons and bosons
- quarks form the nuclei

- Electromagnetic force - mediated by massless photon
- Weak interaction - mediated by bosons : Z, W⁺, W⁻
- Strong interaction - mediated by 8 gluons
- Higgs boson : confers their mass to other particles via symmetry breaking
 - **Discovered at LHC by ATLAS and CMS in 2012 !**
- Gravity
 - Not described by the SM

Going beyond the Standard Model

- Several loopholes in the SM
 - No explanation for ~95% of the content of the universe
 - Dark Matter (~25%), Dark Energy (~70%)
 - Some mathematical inelegancies (fine-tuning problems...)
- Several models go beyond the Standard Model to try and solve these
 - e.g. predict new particles constituting Dark Matter
- In LHC experiments, try to produce directly such new particles and detect their signatures
- Other way of finding hints of New Physics is the very precise measurement of known particles properties, and test their values against the SM predictions
 - Higgs couplings to bosons, quarks and leptons
 - top quark mass, W boson mass
 - ...
- Measurements and searches are led by analysing high energy collisions at the LHC

The LHC (Large Hadron Collider)

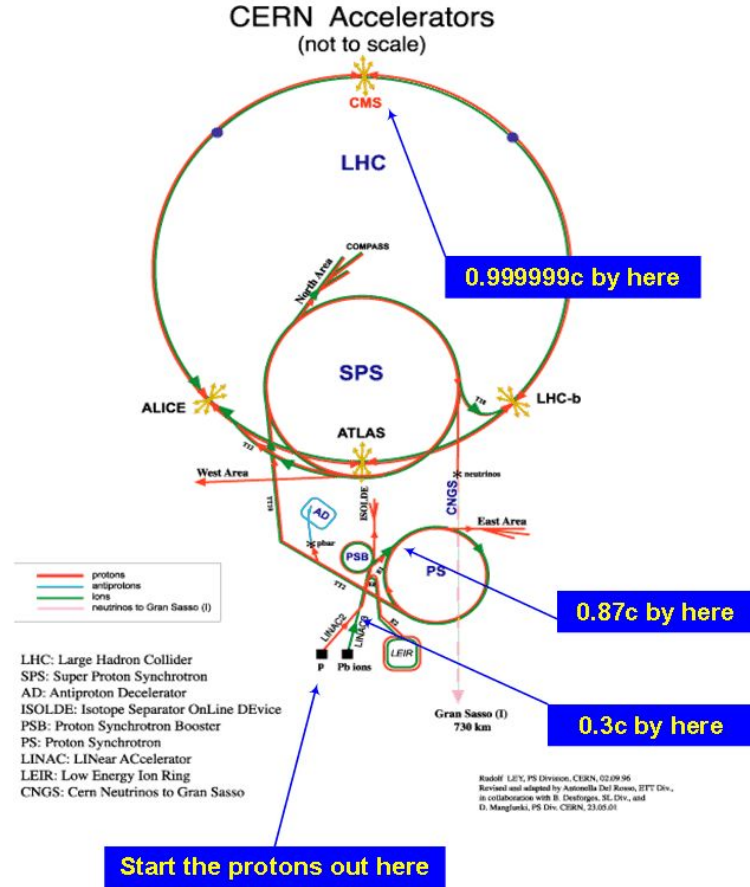

Overall view of the LHC experiments.

- proton-proton collider, in service since 2009-2010
 - Most energetic: reached an energy 13.6 TeV in the centre of mass since 2022
- 27 km of circumference, many superconducting magnets to bend the proton trajectories
- protons grouped in bunches separated in time by 25ns
- 4 points of collision, where detectors are installed: LHCb, ALICE, CMS, ATLAS

The LHC (Large Hadron Collider)

- Before they reach the LHC, the particles are sped up in a series of interconnected linear and circular accelerators
- LHC further accelerates and focuses the proton beams for them to collide at each interaction point
 - 1232 dipole magnets, 15 metres in length, which bend the beams
 - 392 quadrupole magnets, each 5–7 metres long, which focus the beams

The ATLAS detector: A Toroidal LHC ApparatuS

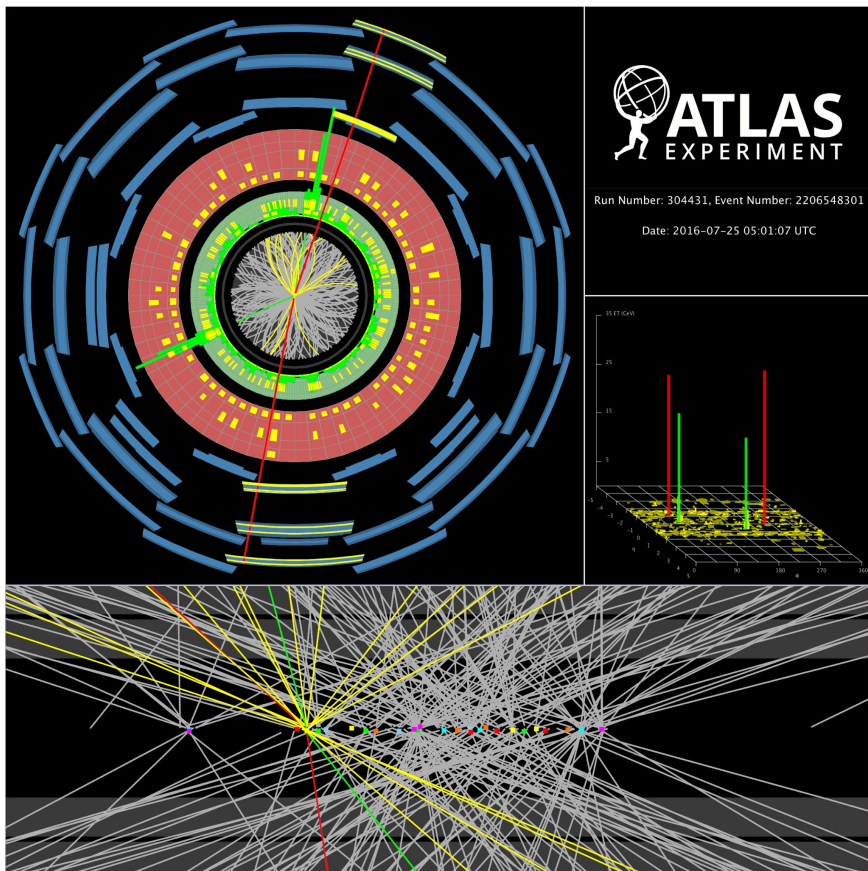

- ATLAS has the dimensions of a cylinder, 46m long, 25m in diameter, weighs 7000 tons and sits in a cavern 100m below ground.
- Main subsystems:
 - Inner Tracking system: charged particles, interaction vertex, secondary vertices
 - Electromagnetic calorimeter : electrons, photons
 - Hadronic calorimeter: 'jets' (quarks and gluons signatures)
 - Muon spectrometer: within a toroidal magnetic field

The ATLAS detector: How we “see” particles

- ATLAS has the dimensions of a cylinder, 46m long, 25m in diameter, weighs 7000 tons and sits in a cavern 100m below ground.
- Main subsystems:
 - Inner Tracking system: charged particles, interaction vertex, secondary vertices
 - Electromagnetic calorimeter : electrons, photons
 - Hadronic calorimeter: ‘jets’ (quarks and gluons signatures)
 - Muon spectrometer: within a toroidal magnetic field

An actual collision seen by ATLAS

- This is what a Higgs boson looks like in ATLAS
- $pp \rightarrow H \rightarrow ZZ^* \rightarrow 2 \text{ electrons} + 2 \text{ muons}$
- “pile-up”: due to the high luminosity, when two proton bunches cross, many other collisions occur (in this case, 25 other collisions)

The ATLAS data taking

- ATLAS records data from colliding proton bunches
 - Bunches collide at a frequency of ~40 MHz
 - Needs to record only the interesting collisions, a.k.a those that produce rare physics process
 - Dedicated and complex trigger system in all detector components, reducing recording rate to ~1kHz
 - i. ATLAS records >10 000 Tb of data per year
 - Detector operation requires a lot of care → reach ~95% recording efficiency

- Data is then sent worldwide to the computing GRID (>130 computing centres)
- Then physics objects (electrons, muons, etc...) are reconstructed via algorithms developed by the collaboration → ready for physics analysis

The ATLAS Collaboration

Status: March 2024

ATLAS Collaboration

185 institutions (253 institutes) from 42 countries

- International collaboration
- ~6000 collaborators, among which ~3000 authors
 - ~1200 PhD students
- More than 1200 papers
- Effort to make data public:
 - <https://atlas.cern/Resources/Opendata>
- Career opportunities:
 - <https://atlas.cern/Discover/Collaboration/Jobs>

Summary - outlooks

- Planning for the coming years
 - Finishing Run3 end of 2025
 - Then entering long technical shutdown (LS3), opportunity to upgrade several parts of the detector
 - HL-LHC era will start with Run4 and beyond, plan to record ~10x more data, with much higher bunch crossing rate

Summary - outlooks

- Many areas to contribute
 - engineering : detector upgrade
 - computing: data storage and processing, new machine-learning applications to data simulation, etc.
 - detector operations
 - object reconstruction and physics studies
- Thanks for your attention!
