# The RHUM\* (Dream) Team

\*Resistive High granUlaritY Micromegas for Future Detectors

# Goals

- Consolidation of resistive pixelised Micromegas, for measurements at high rates - order of  $10 \text{ MHz/cm}^2$ 
  - High-granularity/low occupancy readout on pads of the order of  $\text{mm}^2$
- Robustness and stable operation at high gains
- Performance
  - efficiencies close to 100%
  - spatial resolution below  $100 \mu\text{m}$
  - time resolution below 10 ns
- Demonstration of the scalability of detectors on large surfaces
- Medium/Low-rate Version – Capacitive Sharing
  - K. Gnanvo et al., Nucl. Instrum. Meth. A 1047 (2023) 167782

# Double DLC layer Micromegas Concept

initial goal was to optimize the structure and to explore the complementarity among different configurations → studies conducted on small-scale prototypes

Final configuration: use of resistive foils based on Diamond Like Carbon structures (DLC).

Readout pads are covered by a double layer of DLC with a grid of staggered interconnecting vias for rapid charge evacuation

Typical (optimal) DLC resistivity:  
20 – 40 Mohm/sq

# Towards Large Size Pixelised Micromegas

small size prototypes

active area : 4.8cm x 4.8 cm

segmented in 48 x 16 readout pads

pad size: 1 x 3 mm<sup>2</sup>

medium size prototypes

Two detectors Paddy400-1 and Paddy400-2

active area : 20 cm x 20 cm (40% readout in central part)

Anode plane pad size: 1 x 8 mm<sup>2</sup>

also tested in sandwich config sharing the same cathode

large size prototype

“The Big one”

Paddy-2000: 50 x 40 cm<sup>2</sup>

Readout central region 6.4x6.4 cm<sup>2</sup> with 1x8 mm<sup>2</sup> pads

Surrounding area – 2048 pads, 10x10 mm<sup>2</sup>

# Gain and Rate Capability

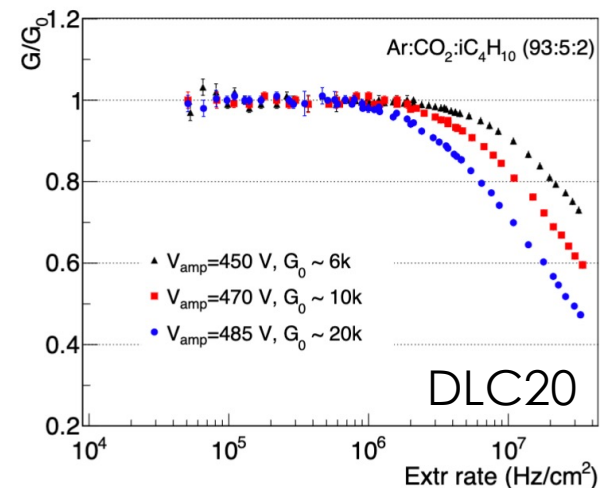

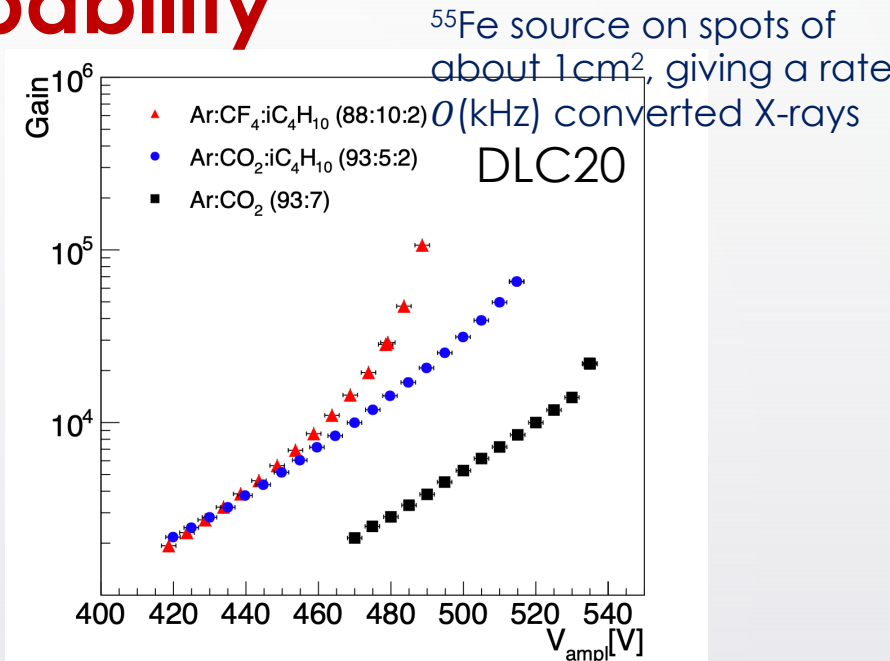

Addition of 2% of isobutane significantly extends the stability range up to  $7 \times 10^4$  and  $10^5$  with Ar:CO<sub>2</sub>:iC<sub>4</sub>H<sub>10</sub> (93:5:2) and Ar:CF<sub>4</sub>:iC<sub>4</sub>H<sub>10</sub> (88:10:2)

guarantee a working point with enough margin

Rate capability Vs X-rays from the copper anode X-Ray gun.

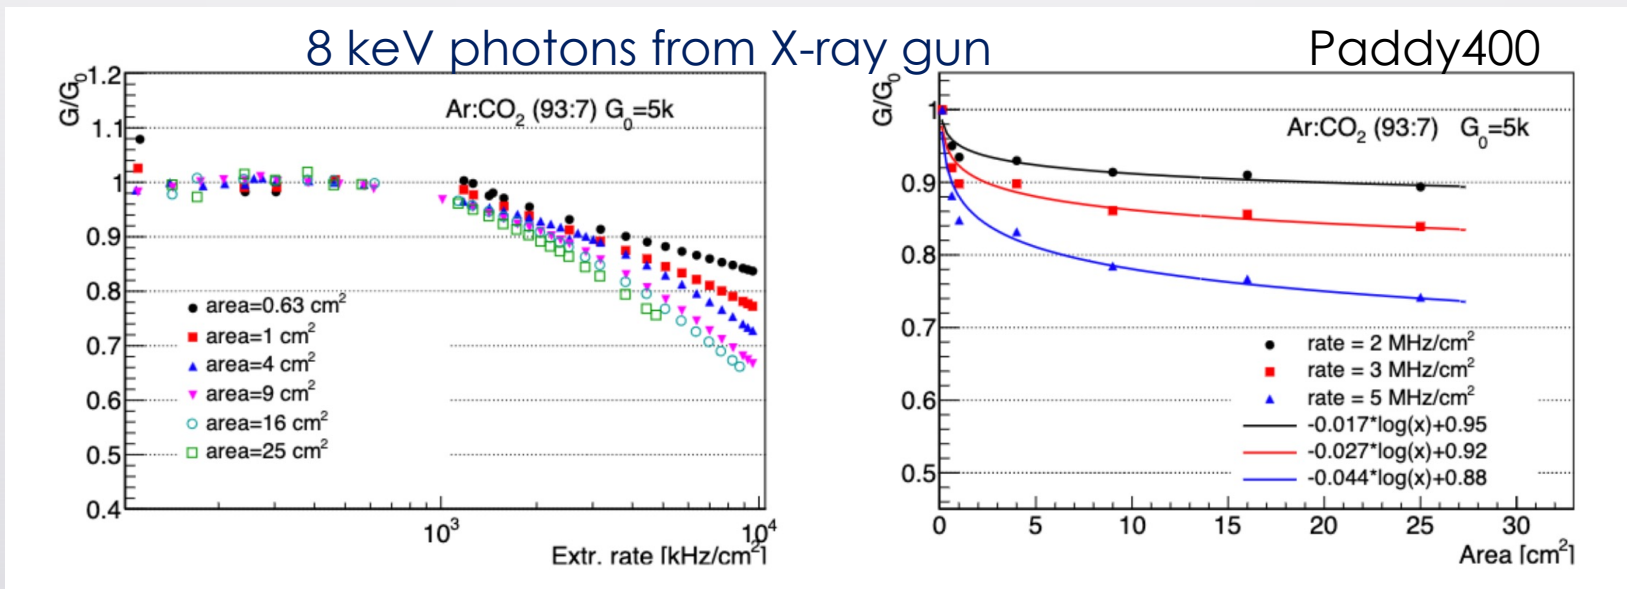

Gain drops at  $10 \text{ MHz/cm}^2$  are limited to 10% at  $G_0 = 6000$

8 keV photons ionization  $\sim 5$  higher than MIP particles  $\rightarrow$  rate capability of order  $10 \text{ MHz/cm}^2$  at a gain of 20k !

# Gain dependence on the irradiated area

- stable behaviour is measured up to about 1 MHz/cm<sup>2</sup>
- empirical logarithmic dependence
- behaviour similar to small DLC prototypes

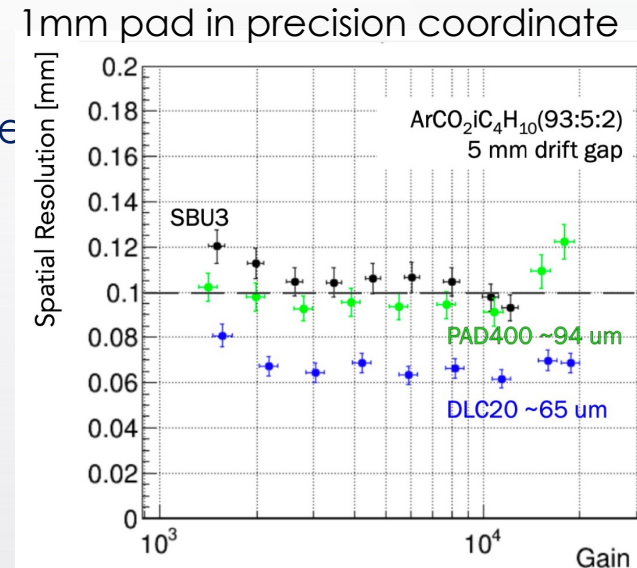

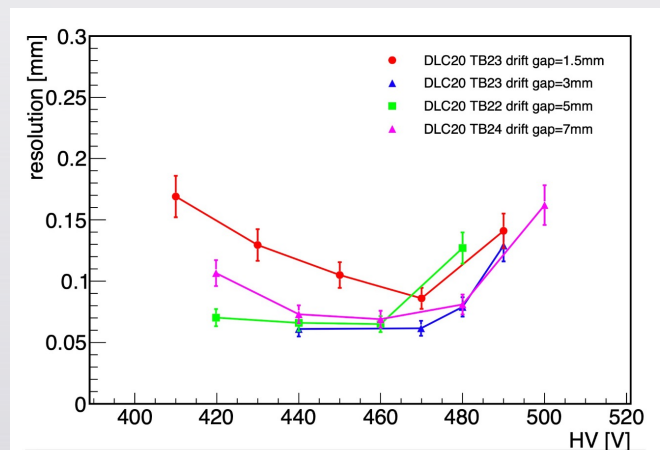

# Spatial Resolution

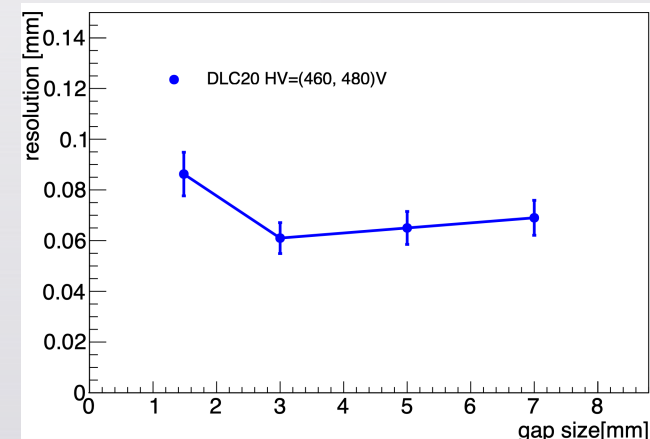

- Unbiased cluster residual wrt extrapolated position from e tracking chambers
  - position from charge weighted cluster centroid
- Extrapolation error is subtracted (about  $50 \mu\text{m}$ ).
- Statistical uncertainty is negligible
- Systematic uncertainty (fit procedure)  $\sim 5\%$

Study of the spatial resolution as a function of the drift gap size shows small dependency

deterioration only for very small drift gap ( $\sim 1.5\text{mm}$ )

for perpendicular tracks

# Spatial resolution- Centroid Optimisation

$$x_c = \frac{\sum x_i q_i^p}{\sum q_i^p}$$

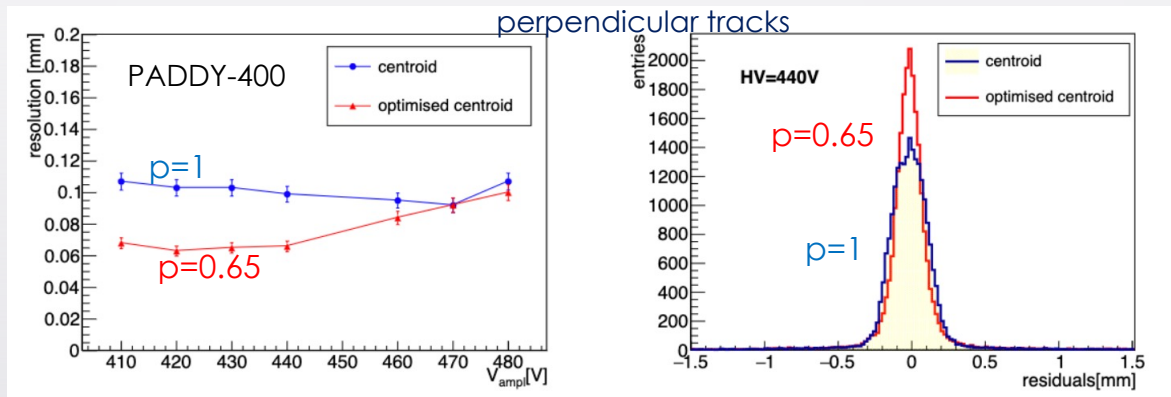

$$x_{trk} = \frac{\sum x_i q_i^p}{\sum q_i^p}$$

The cluster position is evaluated with an extended definition of the charge weighted centroid:

optimal parameter “p” found through a minimisation of residuals

## improvement of ~35%

at high gain the resolution is limited by poor charge measurements in APV due to saturation

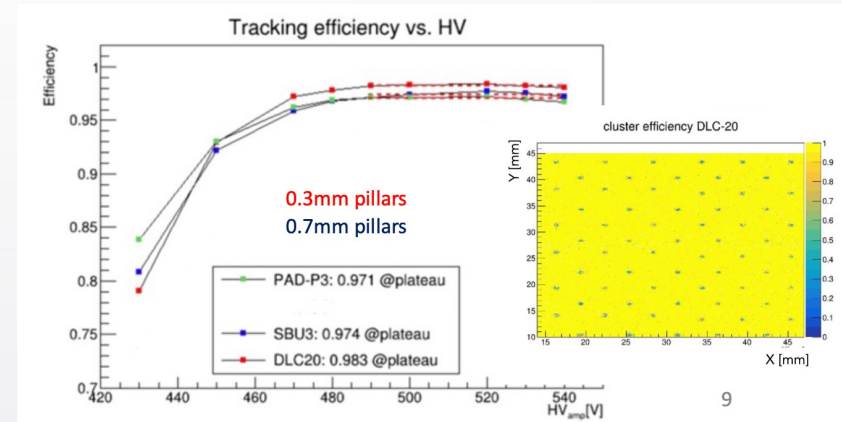

## work in progress

**Under development :**  
**exploit timing information for inclined tracks** → cluster time projection method

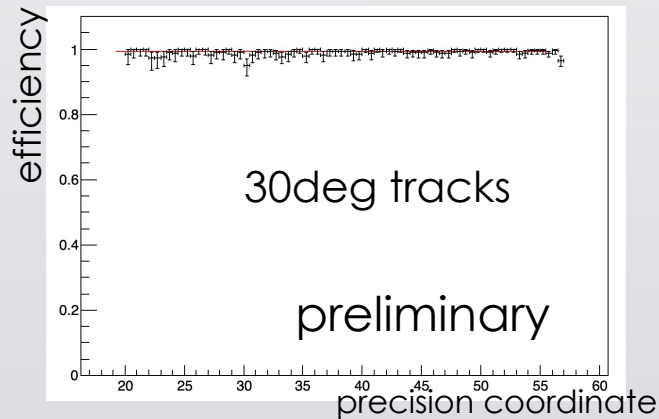

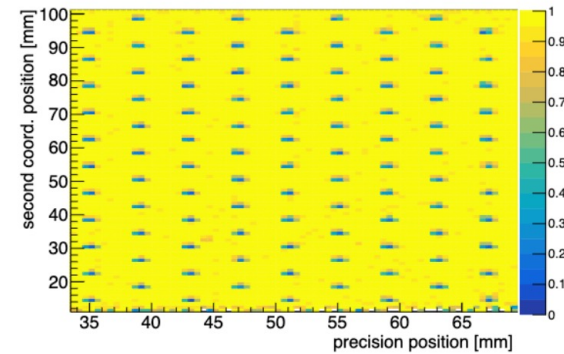

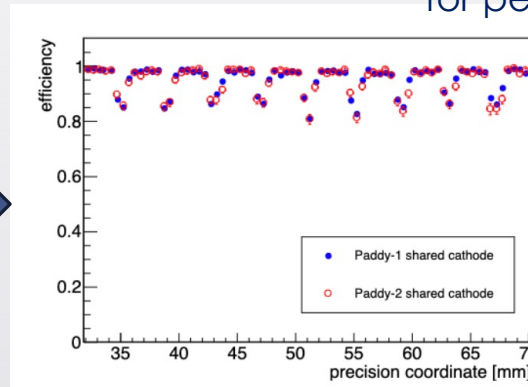

# Efficiencies

- 1.5 mm (on precision coordinate) fiducial cut wrt extrapolated position from external tracking chambers
- Efficiency for perpendicular tracks is nearly 100% except at pillar positions

for perpendicular tracks

efficiencies for Paddy400 with shared cathode

pillars disappear with inclined tracks

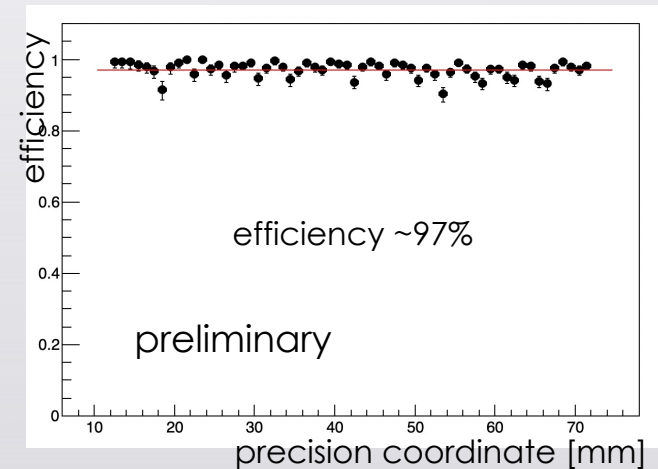

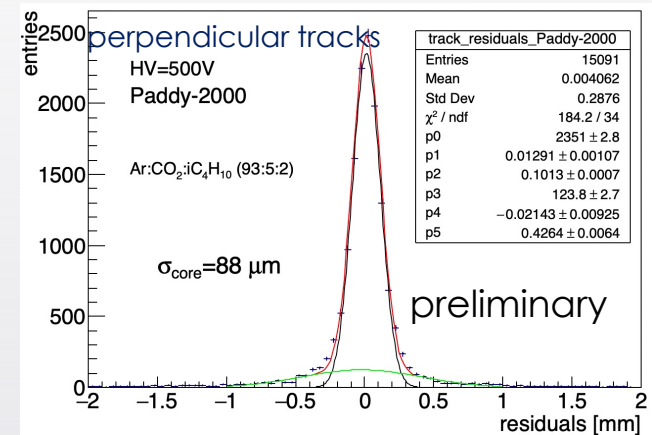

# Paddy-2000 – the “Big One”

tested for the first time in 2024 Test Beam in April

shows similar performance as small prototypes

full analysis of TB data in progress

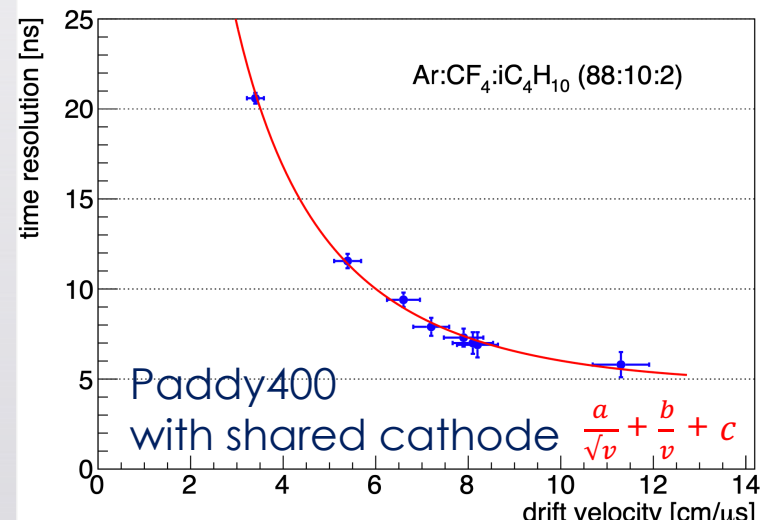

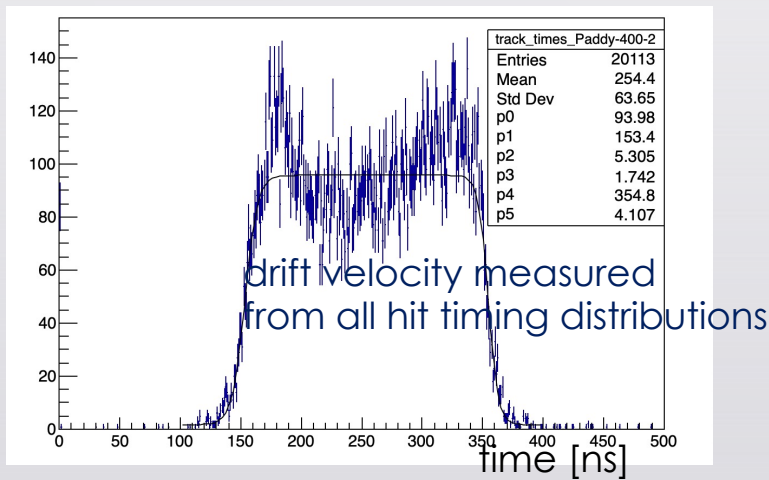

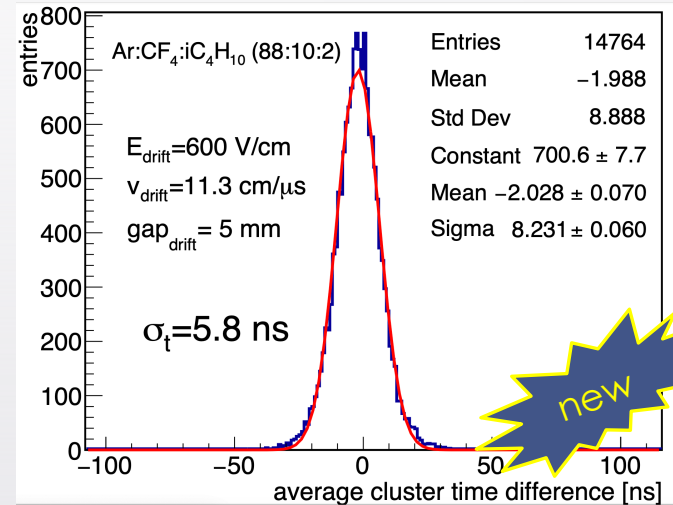

# Time resolution

Method: compute the time difference between on-track clusters in two different chambers

Gaussian fit performed to each time difference distribution, time resolution evaluated as  $\sigma/\sqrt{2}$

Improved analysis (mainly better definition of detector fiducial region) → Paddy400 time resolution ~ 6 ns at  $v_{\text{drift}} \sim 11 \text{ cm}/\mu\text{s}$   
[fast gas mixture, includes effects from electronics/APV q(t) distribution fit]

# Capacitive Sharing Chamber

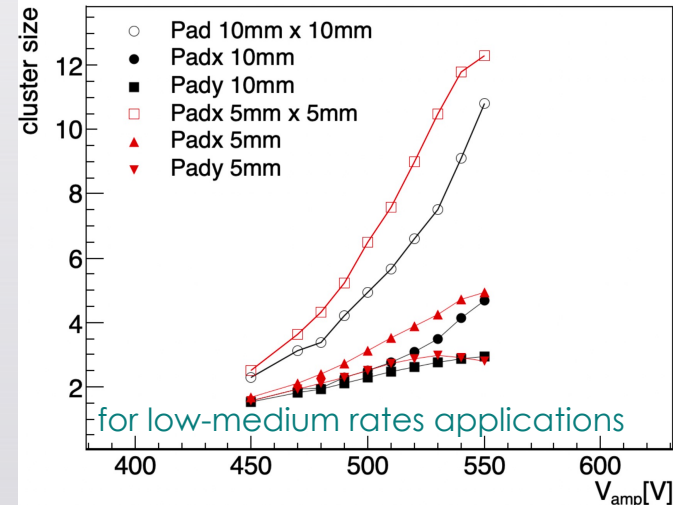

charge shared in large readout pads using capacitive coupling between stack of layers of pads → spatial resolution and reduction of readout channels

Pad size of "top-layer"  
(signal induction):  $2.5 \times 2.5 \text{ mm}^2$

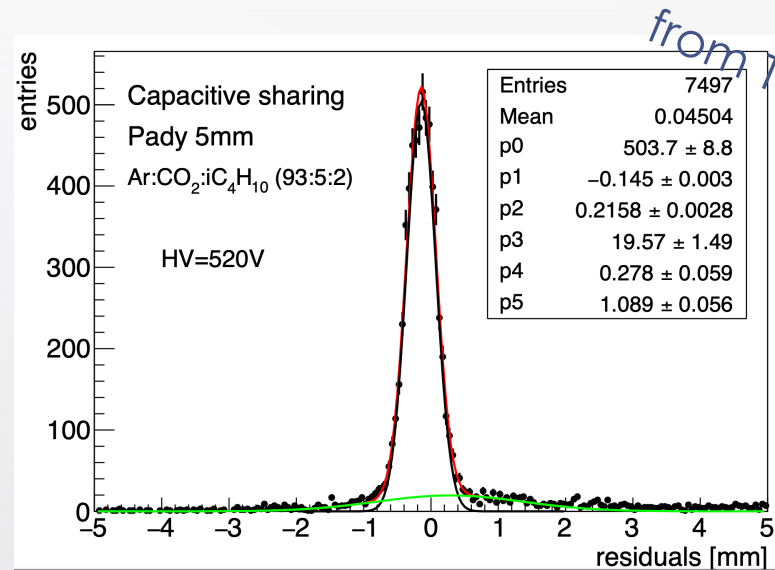

Side-L: three layers capacitive sharing:  $2.5 \times 2.5 \text{ mm}^2$   
→  $5 \times 5 \text{ mm}^2$  →  $10 \times 10 \text{ mm}^2$

Side-S: two layers capacitive sharing:  
 $2.5 \times 2.5 \text{ mm}^2$  →  $5 \times 5 \text{ mm}^2$

for low-medium rates applications

# Capacitive Sharing Spatial Resolution

from TB24 in April

large pad resolution  $\sim 320 \mu\text{m}$   
 $\rightarrow$  factor 1/30 of the pad size

small pad resolution  $\sim 200 \mu\text{m}$   
 $\rightarrow$  factor 1/20 of the pad size

typical without capacitive sharing  
 $\sim 1/14$  of the pad size

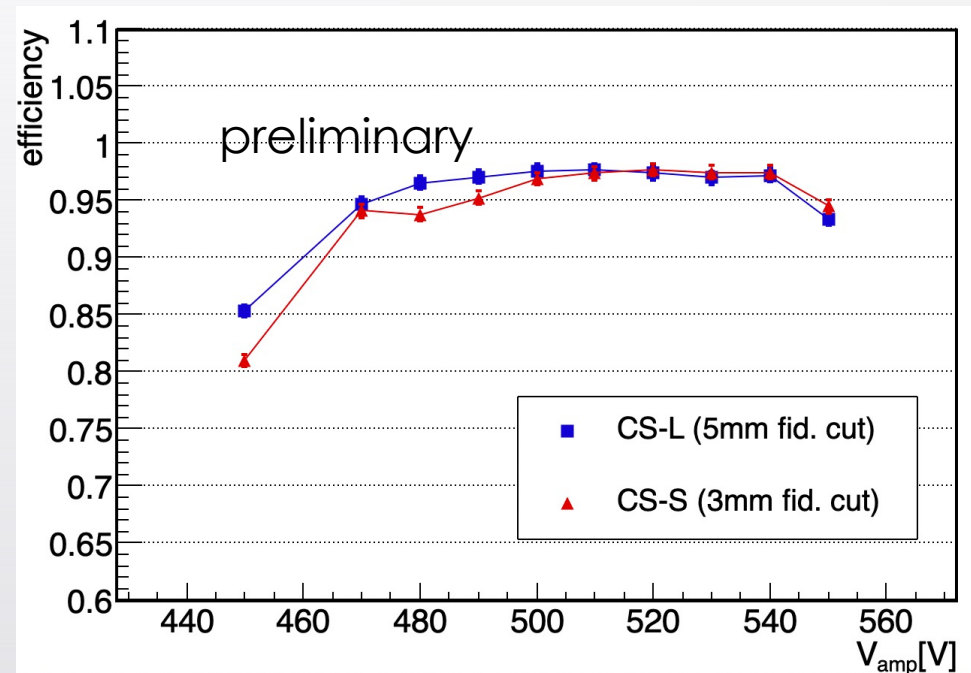

new

# Capacitive Sharing Efficiencies

Efficiencies around ~97%

compatible with the “standard”  
prototypes

new

# Summary and Outlook

16

- Started in 2015, the R&D on high performance resistive Micromegas achieved all the objectives of the project and is aligned with the ECFA Roadmap implemented in the DRD1
- The R&D is approaching the strategic themes of DRD1 WP1 for large systems for future experiments, namely (task 2 deliverables):
  - high rate applications : high gain to ensure stability providing a good margins, and rate capability ✓
  - low/medium rate applications : R&D on capacitive sharing started – promising results !
  - space and time resolution ✓
  - scalability for large area apparatuses → construction and test of large size detector (50x40 cm<sup>2</sup>) ongoing – promising results!
  - simplifications and cost reduction
    - simplified DLC structures, larger readout elements (exploiting both resistive and capacitive sharing)
    - Production at Industry (ELTOS) is being investigated → last week we have successfully built small size prototypes with DLC and the bulk technique ✓
- Addressing FE electronics and DAQ for high rate operations is crucial → the Topical Workshop on Wednesday will be a good check point

# Cheers from Eltos...

first production (2 small prototypes) done  
to be tested

**next steps : larger size prototypes!**
