Top quark production at LHC

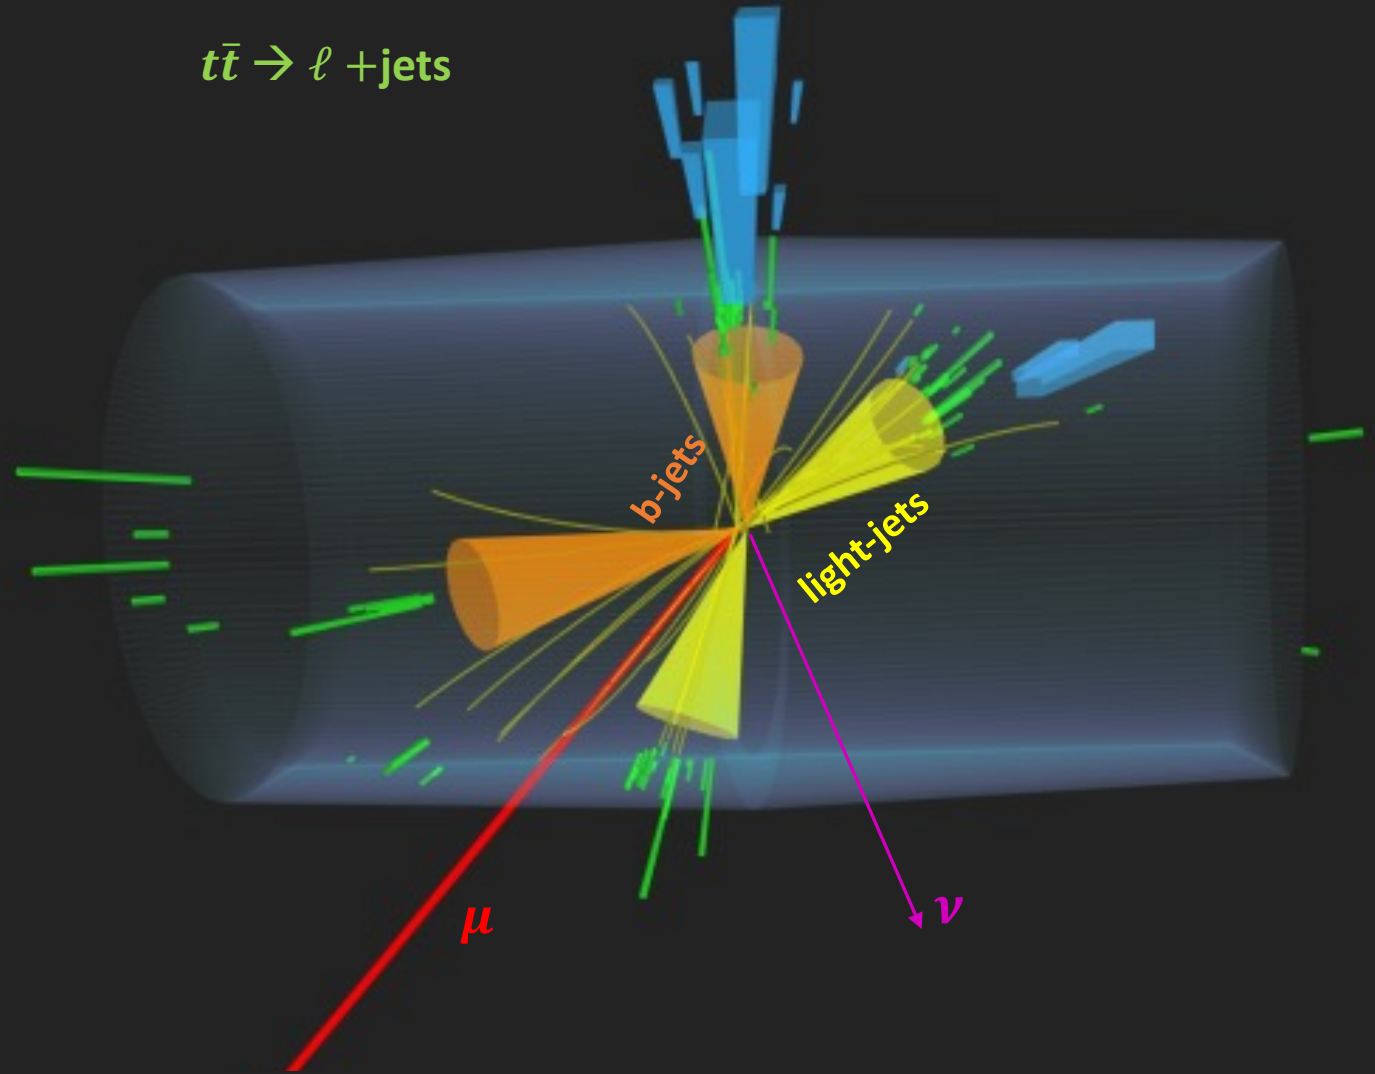

Top quarks mainly produced in pairs

$$B(t \rightarrow Wb) \sim 100\%$$

$$t\bar{t} \rightarrow \ell + \text{jets}$$

80-90% efficiency to correctly assign the top-decay products using m_W and m_{top}

Top quark polarization and spin correlation

- Top-pairs @LHC are mainly unpolarized (parity invariance of QCD)
- Their spins are strongly correlated

$$\begin{array}{l} \text{lifetime} < \text{QCD timescale} << \text{Spin-flip timescale} \\ 10^{-25}\text{s} < 10^{-24}\text{s} << 10^{-21}\text{s} \end{array}$$

- Spin information is passed onto ℓ^\pm and d -quark
 \rightarrow preferentially radiated in the top spin direction

- Many NP models modify spin polarization and correlation of top quarks

- New mediator ?
- New particles decaying to tops ?

...but also interesting for testing the foundations of Quantum physics

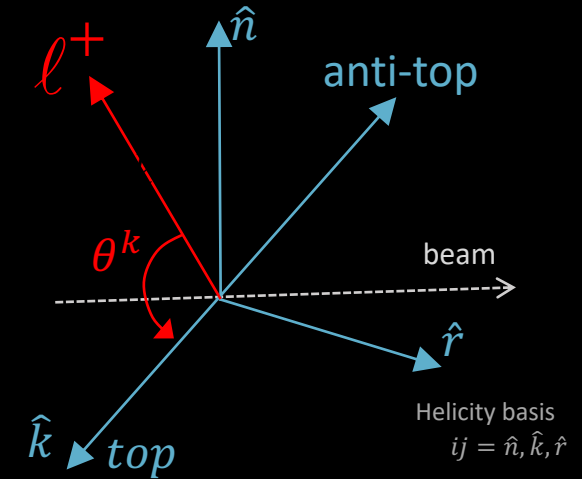

Top quark polarization and spin correlation

$t\bar{t}$ production cross section parametrized vs polarization & spin correlation coefficients

$$\frac{1}{\sigma} \frac{d\sigma}{d \cos \theta_+^i d \cos \theta_-^j} = \frac{1}{2} (1 + \mathbf{B}_+^i \cos \theta_+^i + \mathbf{B}_-^j \cos \theta_-^j - \mathbf{C}_{ij} \cos \theta_+^i \cos \theta_-^j)$$

$$\mathbf{B}_\pm = \begin{pmatrix} x \\ x \\ x \end{pmatrix} \quad \mathbf{C} = \begin{pmatrix} x & x & x \\ x & x & x \\ x & x & x \end{pmatrix}$$

6 polarization and 9 spin correlation coefficients can be extracted from differential measurements

\hat{k} : top-quark direction in $t\bar{t}$ CMF ("helicity")
 \hat{n} = normal to $t\bar{t}$ scattering plane ("transverse")
 \hat{r} = normal to \hat{k} in $t\bar{t}$ scattering plane

Observation of quantum entanglement in top-quark pairs using the ATLAS detector

The ATLAS Collaboration

We report the highest-energy observation of entanglement, in top-antitop quark events produced at the Large Hadron Collider, using a proton-proton collision data set with a center-of-mass energy of $\sqrt{s} = 13$ TeV and an integrated luminosity of 140 fb^{-1} recorded with the ATLAS experiment. Spin entanglement is detected from the measurement of a single observable D , inferred from the angle between the charged leptons in their parent top- and antitop-quark rest frames. The observable is measured in a narrow interval around the top-antitop quark production threshold, where the entanglement detection is expected to be significant. It is reported in a fiducial phase space defined with stable particles to minimize the uncertainties that stem from limitations of the Monte Carlo event generators and the parton shower model in modelling top-quark pair production. The entanglement marker is measured to be $D = -0.547 \pm 0.002$ (stat.) ± 0.021 (syst.) for $340 < m_{\bar{t}t} < 380$ GeV. The observed result is more than five standard deviations from a scenario without entanglement and hence constitutes both the first observation of entanglement in a pair of quarks and the highest-energy observation of entanglement to date.

CMS-TOP-23-001

Observation of quantum entanglement in top quark pair production in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration*

Abstract

Entanglement is an intrinsic property of quantum mechanics and is predicted to be exhibited in the particles produced at the Large Hadron Collider. A measurement of the extent of entanglement in top quark-antiquark ($t\bar{t}$) events produced in proton-proton collisions at a center-of-mass energy of 13 TeV is performed with the data recorded by the CMS experiment at the CERN LHC in 2016, and corresponding to an integrated luminosity of 36.3 fb^{-1} . The events are selected based on the presence of two leptons with opposite charges and high transverse momentum. An entanglement-sensitive observable D is derived from the top quark spin-dependent parts of the $t\bar{t}$ production density matrix and measured in the region of the $t\bar{t}$ production threshold. Values of $D < -1/3$ are evidence of entanglement and D is observed (expected) to be $-0.480^{+0.029}_{-0.029}$ ($-0.467^{+0.029}_{-0.029}$) at the parton level. With an observed significance of 5.1 standard deviations with respect to the non-entangled hypothesis, this provides observation of quantum mechanical entanglement within $t\bar{t}$ pairs in this phase space. This measurement provides a new probe of quantum mechanics at the highest energies ever produced.

Measurements of polarization, spin correlations, and entanglement in top quark pairs using lepton+jets events from pp collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration

Abstract

Measurements of the polarization and spin correlations in top quark pairs ($t\bar{t}$) are presented using events with a single electron or muon and jets in the final state. The measurements are based on proton-proton collision data from the LHC at $\sqrt{s} = 13$ TeV collected by the CMS experiment, corresponding to an integrated luminosity of 138 fb^{-1} . All coefficients of the polarization vectors and the spin correlation matrix are extracted simultaneously by performing a binned likelihood fit to the data. The measurement is performed in bins of additional observables such as the mass of the $t\bar{t}$ system and the top quark scattering angle. Inclusive coefficients are obtained by combining the results of all fitted bins. From the measured spin correlations, conclusions on the $t\bar{t}$ spin entanglement are drawn. The standard model predicts entangled spin $t\bar{t}$ states at the production threshold and at high masses of the $t\bar{t}$ system. Entanglement is observed for the first time in events with high $t\bar{t}$ mass, with an observed (expected) significance of 6.7 (5.6) standard deviations. The observed level of entanglement cannot be explained by classical exchange of information between the two particles alone. The observed (expected) significance for entanglement attributable to space-like separated $t\bar{t}$ pairs is 5.4 (4.1) standard deviations.

Entanglement between a pair of top quarks

Entanglement is a purely quantum phenomenon that has been observed in a wide range of systems, from photons to atoms. The observation of quantum entanglement between the heaviest known fundamental particles, top quarks, at the highest energies ever produced is a significant discovery. This is the highest energy measurement of quantum entanglement and could open new windows into the nature of quantum mechanics at very high energies. The top quark is produced in pairs in proton-proton collisions at the LHC, and the observation of entanglement between a pair of top quarks is a significant discovery. This is the highest energy measurement of quantum entanglement and could open new windows into the nature of quantum mechanics at very high energies. The top quark is produced in pairs in proton-proton collisions at the LHC, and the observation of entanglement between a pair of top quarks is a significant discovery.

Entanglement in $t\bar{t}$

- Spin correlation is $m(t\bar{t})$ and $\cos \theta$ dependent
 → Entanglement in some phase-space regions

- $t\bar{t}$ in mixed states (eg. $|\Psi\rangle = \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle)$) → two qubit system
- Peres–Horodecki criterion for entanglement

$$\Delta_E = C_{nn} + |C_{rr} + C_{kk}| > 1$$

$$C = \begin{pmatrix} x & & \\ & x & \\ & & x \end{pmatrix}$$

Entanglement in $t\bar{t}$

- Spin correlation is $m(t\bar{t})$ and $\cos \theta$ dependent
- Entanglement in some phase-space regions

- $t\bar{t}$ in mixed states (eg. $|\Psi\rangle = \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle)$) → two qubit system
- Peres–Horodecki criterion for entanglement

$$\Delta_E = C_{nn} + |C_{rr} + C_{kk}| > 1$$

Low $m(t\bar{t})$: $D = -\frac{\Delta_E}{3} < -\frac{1}{3}$

$gg \rightarrow t\bar{t} (^1S_0)$

High $m(t\bar{t})$: $\tilde{D} = \frac{\Delta_E}{3} > \frac{1}{3}$

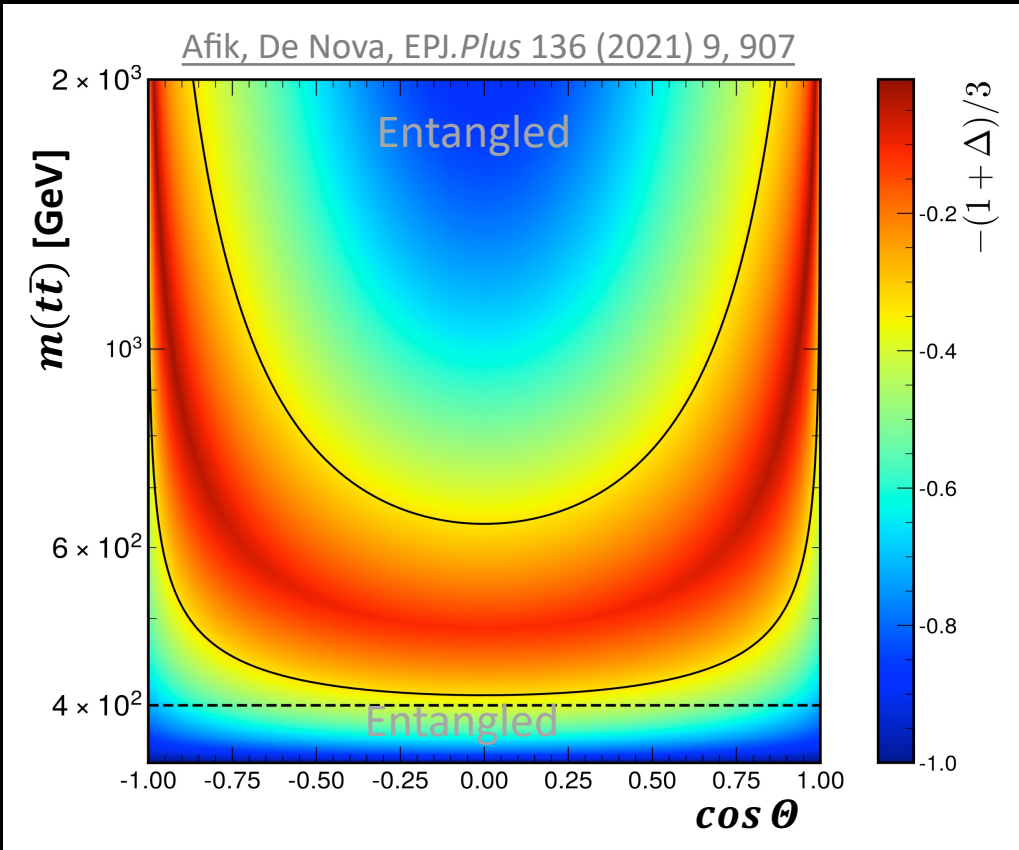

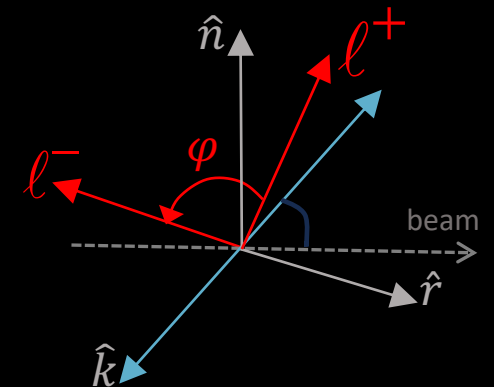

$gg/qq \rightarrow t\bar{t} (^3S_1)$

Extract D and \tilde{D} from single differential measurement

$$\frac{1}{\sigma} \frac{d\sigma}{d \cos \varphi} = \frac{1}{2} (1 + D \cos \varphi)$$

$$\cos \varphi = \hat{\ell}^+ \cdot \hat{\ell}^-$$

$\hat{\ell}$: unit vector in top rest frame

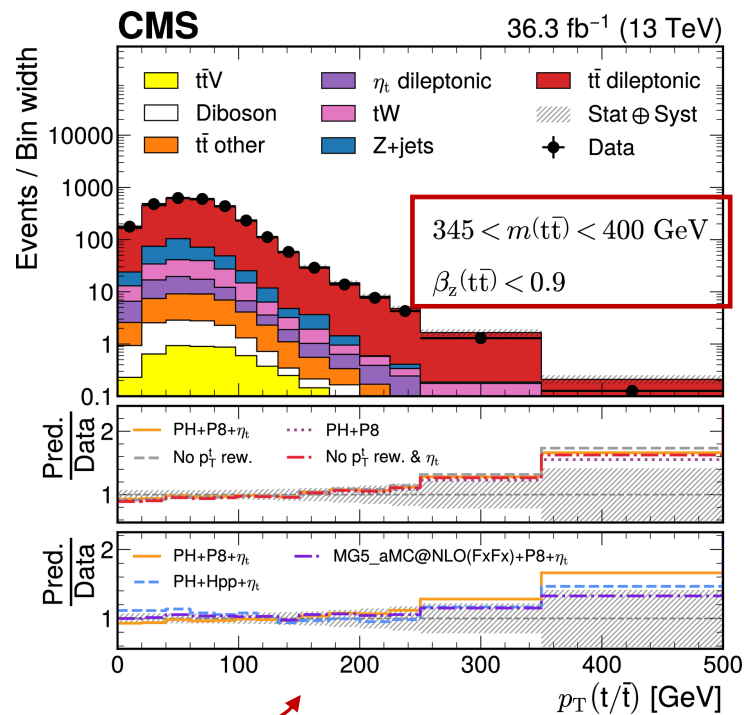

Entanglement in $t\bar{t}$ (dilepton channel)

$$\cos \varphi = \hat{\ell}^+ \cdot \hat{\ell}^-$$

- 2016 data
- $e\mu, ee, \mu\mu$ channels, 2 jets ≥ 1 bjet
- Top reconstruction assuming $p_T^{miss} = p_T^{\nu 1} + p_T^{\nu 2}$, m_W and m_t
- Solution with lowest $m_{t\bar{t}}$ is taken, 90% efficiency
- $m_{t\bar{t}} < 400 \text{ GeV}$, $\beta_z(t\bar{t}) < 0.9$ to enhance $\frac{gg}{qq}$

Focus on low $m_{t\bar{t}}$

Entanglement in $t\bar{t}$ (dilepton channel)

$$\cos \varphi = \hat{\ell}^+ \cdot \hat{\ell}^-$$

Signal simulation

- POWHEG+Pythia8 @NLO QCD
- TOP++ for x-section @NNLO QCD
- EWK corrections @NLO with Higgs exchange
- $p_T(\text{top})$ reweighting to match the top quark p_T spectrum from a fixed order ME calculation at NNLO

- Different degrees of spin-correlation via mixture of samples with/without SC
- Binned likelihood fit to $\cos \varphi$ to extract D at parton level

Entanglement in $t\bar{t}$ (dilepton channel)

$$\cos \varphi = \hat{\ell}^+ \cdot \hat{\ell}^-$$

Entanglement in $t\bar{t}$ is observed with $>5\sigma$ at low $m_{t\bar{t}}$

Entanglement in $t\bar{t}$ (dilepton channel)

$$\cos \varphi = \hat{\ell}^+ \cdot \hat{\ell}^-$$

Include $t\bar{t}$ bound-state: toponium (η_t)*

- Pseudoscalar & maximally entangled
- $m(\eta_t) = 343 \text{ GeV}$
- $\sigma(pp \rightarrow \eta_t) = 6.43 \pm 0.90 \text{ pb}$

Entanglement in $t\bar{t}$ is observed with $>5\sigma$ at low m_{tt}

Main uncertainties:

- η_t normalization
- Jet energy calibrations
- Statistical
- Modeling of $t\bar{t}$ production/decay

See E. Gallo's talk for more on toponium

Entanglement in $t\bar{t}$ ($\ell + jets$ channel)

- $e/\mu + 4 jets, \geq 1 bjets$
- Better sensitivity at **high $m_{t\bar{t}}$**
- Spin information via ℓ/d -quark

$$\cos \varphi = \hat{\ell} \cdot \hat{d}$$

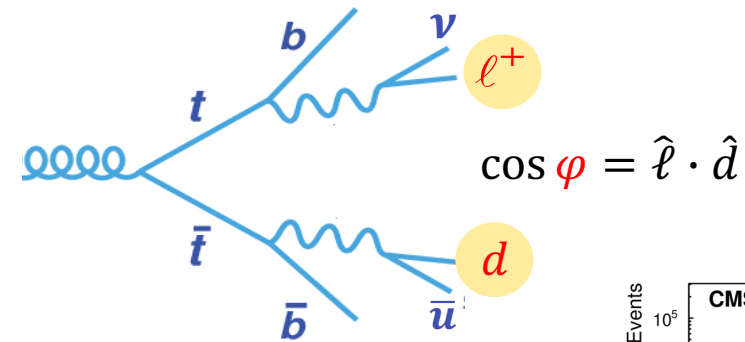

- NN for correct assignment of top decay products (**up to 50% correct assignment including d-type quark jet**)

Fraction of correctly reconstructed events including d-quark

Entanglement in $t\bar{t}$ ($\ell + jets$ channel)

- Events are categorized according to e/m , N_{jets} , and NN score
- Profile likelihood fits to $\cos \varphi$ in bins of $m(t\bar{t})$ and $|\cos \theta|$ in each event category

Pre-fit

Post-fit

Low $m(t\bar{t})$ \longrightarrow High $m(t\bar{t})$

Extract the coefficients for polarisation vectors (B_{\pm}^i), spin correlation matrix (C_{ij}) as well as \mathbf{D} and $\tilde{\mathbf{D}}$

Polarization and Spin Correlation coefficients

$$B_{i+} = \begin{pmatrix} x \\ x \\ x \end{pmatrix}$$

$$C = \begin{pmatrix} x & x & x \\ x & x & x \\ x & x & x \end{pmatrix}$$

- Measured the coefficients for polarization and spin-correlation in inclusive and various kinematic phase-space
- So far measurements agree with the SM predictions

Entanglement in $t\bar{t}$ ($\ell + jets$ channel)

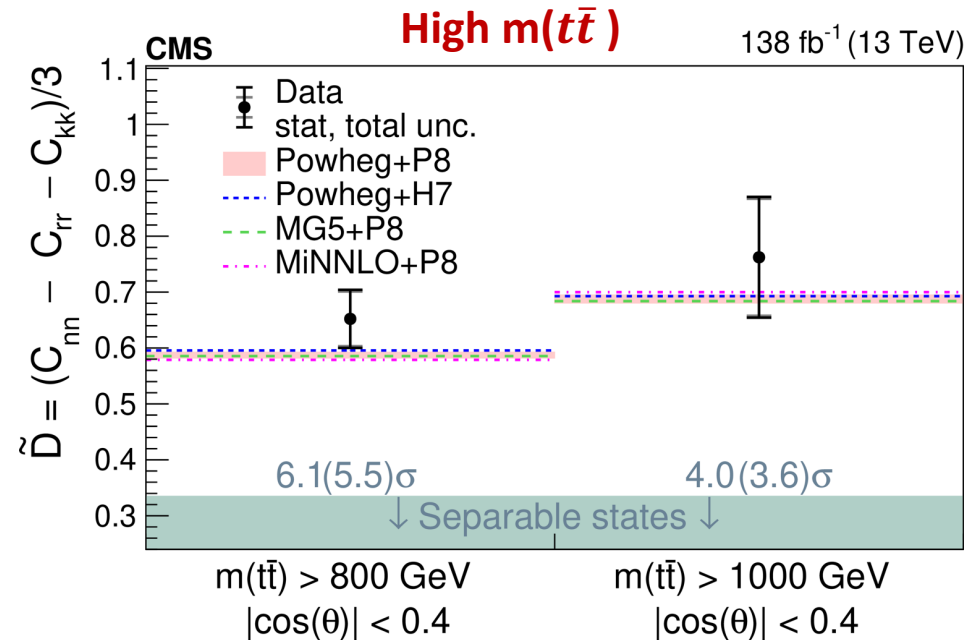

- Entanglement is established at **high $m(t\bar{t})$** **for the first time with $>5\sigma$**
- Complementarity wrt. dilepton channel

Entanglement in $t\bar{t}$ ($\ell + jets$ channel)

- Entanglement is established at **high $m(t\bar{t})$** **for the first time with $>5\sigma$**
- Complementarity wrt. dilepton channel

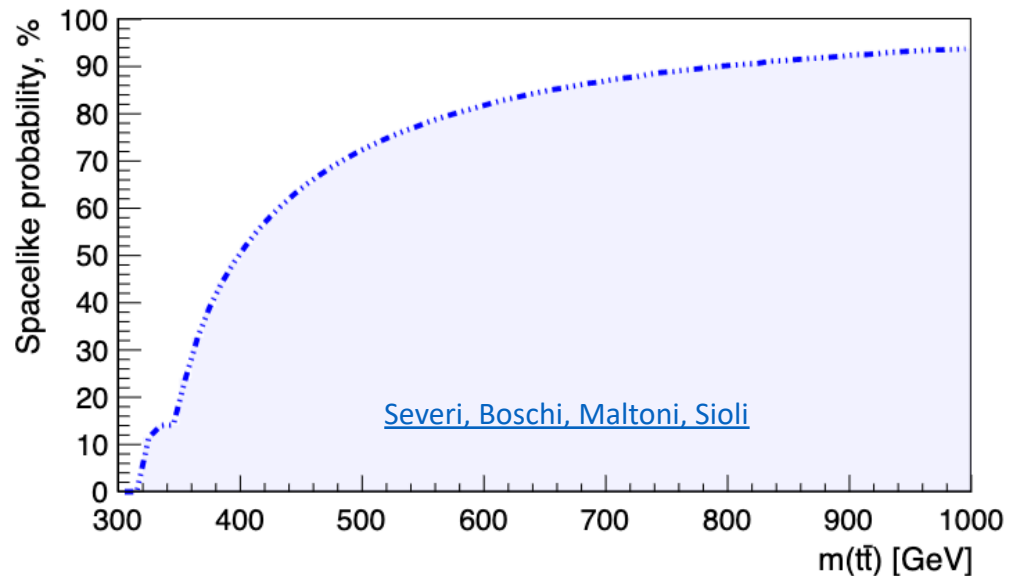

Entanglement in $t\bar{t}$ ($\ell + jets$ channel)

- Entanglement is established at **high $m(t\bar{t})$** **for the first time with $>5\sigma$**
- Complementarity wrt. dilepton channel

Fraction of events with space-like separation increases with $m(t\bar{t})$

Didar Dobur, Ghent university

Entanglement at **high $m(t\bar{t})$**
 → space-like separated region
 → prospects for Bell inequality tests

A new window to look for new physics effects

Severi, et al [2210.09330](#)

Summary

- Entanglement in top quark pairs is observed with $> 5\sigma$
 - Multiple analyses in different phase-space regions!
 - Detailed measurements of polarization coefficients and spin density matrix
- Exciting sensitivity to toponium state!
- A new experimental tool to search for new physics!

Excluding classical explanation ?

- What is the maximum value of ΔE that can still be explained by the non-quantum communication ($v \leq c$)?
- In this case only t and \bar{t} decays separated by a time-like interval are entangled
- The rest of the events must be separable

- $t\bar{t}$ decay vertices are not observed, the fraction of space-like events, f , can only be determined statistically

→ Form a new Δ_E threshold

$$\text{Max}(|C_{ii}|) = 1$$

$$\Delta_{E_{critical}} = f(\Delta_E = 1) + (1-f)(\Delta_E = 3)$$
