## A History of Physical Theories

Figure: The cube of physical theories, with the Theory of Everything in blue and Non-Relativistic Quantum Gravity in red.

- It has been a long-term goal to couple gravity with quantum mechanics.
- Modern physical theories aim to unify three concepts: Relativity (c), Quantum Theory (ħ), and Gravity (G).
- With no Theory of Everything found, we can look towards the other unknown: Non-Relativistic Quantum Gravity.

### The Newton-Schrödinger Equation

- Originally defined by Diósi, then Penrose. The Newton-Schrödinger System gives us an approach to Non-Relativistic Quantum Gravity.
- 2. Topic of 1 master's thesis, 2 PhD theses, and numerous papers in multiple sub-fields.
- 3. Defined by 2 equations: The Time-Dependent Schrödinger equation with gravitational potential,

$$i\hbar\frac{\partial\Psi}{\partial t} = -\frac{\hbar^2}{2m}\nabla^2\Psi + m\Phi\Psi$$

and the Poisson equation

$$\nabla^2 \Phi = 4\pi \, Gm |\Psi|^2$$

# Our Goal

Previous studies focused on simple wavefunctions in spherical symmetry. So, we will seek to answer 3 new questions:

- 1. How does the NS System behave in other domains, like a circle?
- 2. How does the NS System behave with multi-peaked initial conditions?
- 3. How do test particles behave in the NS System?

#### The NS Equations in Dimensionless Coordinates

1. Firstly, let us rescale the system using three fundamental constants:

$$I_{NS} = \frac{\hbar^2}{m^3 G}, \quad m_{NS} = m, \quad t_{NS} = \frac{\hbar^3}{m^5 G^2}$$

2. Final NS System in dimensionless coordinates:

$$i\frac{\partial\Phi}{\partial t} = -\frac{1}{2}\nabla^2\Psi + \Phi\Psi, \quad \nabla^2\Phi = |\Psi|^2$$

3. Our initial value problem: Constants A, B, momentum  $p_i$ , initial angle  $\theta_i$ , and initial width  $\sigma_i$ 

$$\Psi(0,\theta) = e^{-A\left(\frac{\theta-\theta_0}{\sigma_0}\right)^2 + ip_0\theta - B\left(\frac{\theta-\theta_1}{\sigma_1}\right)^2 + ip_1\theta}$$

# The System on a Circle

#### 1. Circular boundary conditions:

2. NS System through  $\nabla$  becomes one-dimensional:

$$i \frac{\partial \Phi}{\partial t} = -\frac{1}{2} \frac{d^2}{d\theta^2} \Psi + \Phi \Psi$$
  
 $|\Psi|^2 = \frac{d^2}{d\theta^2} \Phi$ 

3. Four initial conditions: Single peak, double peak with equal spacing, double peak with unequal spacing, double peak with different sizes.

# Solving for Gravitational Potential

Multiple approaches exist:

- 1. In general: Use iterative methods like the Conjugate Gradient or UMFPACK matrix equation solvers.
  - (i) Discretize the derivative:

$$rac{d^2\Phi}{d heta^2} = rac{\Phi_{i+1}-2\Phi_i+\Phi_{i-1}}{(\Delta heta)^2}$$

(ii) Rewrite our equation:

$$rac{\Phi_{i+1}-2\Phi_i+\Phi_{i-1}}{(\Delta heta)^2}=|\Psi|^2$$

(iii) Represent this as an  $M \times M$  tri-diagonal matrix A.

- (iv) Implement Boundary conditions: The corners of A must also be Φ/(Δθ)<sup>2</sup> for the first and last points to interact.
  (v) Solve the linear equation AΦ = |Ψ|<sup>2</sup>.
- 2. Alternatively, use a spectral method (The Fourier Transform).

Results

#### The Crank-Nicolson Method Numerically

- For time-evoltion we use the Crank-Nicolson Method: A normalization-preserving multi-step model.
- The time derivative is simple to modify:

$$\frac{\partial \Psi}{\partial t} = \frac{\Psi_i^{n+1} - \Psi_i^r}{\Delta t}$$

For space derivatives, each piece of the equation:

$$\begin{split} \frac{\partial^2 \Psi}{\partial \theta^2} &= \frac{1}{2(\Delta \theta)^2} \left( \begin{bmatrix} \Psi_{i+1}^{n+1} - 2\Psi_i^{n+1} + \Psi_{i-1}^{n+1} \end{bmatrix} \\ &+ \begin{bmatrix} \Psi_{i+1}^n - 2\Psi_i^n &+ \Psi_{i+1}^n \end{bmatrix} \right) \\ \frac{\partial \Psi}{\partial \theta} &= \frac{1}{\Delta \theta} \left( \begin{bmatrix} \Psi_{i+1}^{n+1} - \Psi_i^{n+1} \end{bmatrix} + \begin{bmatrix} \Psi_{i+1}^n - \Psi_i^n \end{bmatrix} \right) \\ \Phi \Psi &= \frac{\Phi_i^n}{2} \left( \Psi_i^{n+1} + \Psi_i^n \right) \end{split}$$

#### **Test Particles**

- Finally, how do test particles move within the system, assuming they don't impact the system itself?
- Define the position of a test particle as X.
- Write a formula for its acceleration:

$$rac{d^2 X}{dt^2} = -
abla \Phi o rac{X^{i+1}-2X^i+X^{i-1}}{(\Delta t)^2} = -
abla \Phi$$

Rewrite to solve iteratively:

$$X^{n+1} = 2X^n - X^{n-1} - \frac{(\Delta t)^2}{m_t} \nabla \Phi^n$$

- The Newton-Schrödinger equation provides an interesting model.
- By using this model, we can estimate how a wave behaves under its own gravity.

What we see:

- 1. With 2 equally sized peaks: They bounce in place.
- 2. With 2 unequally spaced peaks: They merge together, producing successive peaks.
- 3. Test particles move towards the closest gravitational point, unless both directions are equally as attractive, in which they are stationary.
