

# CFD Results Update

Damiano 13/06/24

$$v = 2 \left[ \frac{m}{s} \right]$$

$$S = \frac{\pi D^2}{4} * \left( \frac{1}{4} \right) = 4.41e - 3 [m^2]$$

$$V = 2 * v * S = 1.76e - 2 \left[ \frac{Nm^3}{s} \right]$$

*Converting from  
[m<sup>3</sup>/s] to [m<sup>3</sup>/h]*

$$V = 63 \left[ \frac{Nm^3}{h} \right]**$$

# Last Week Results

- The flowrate (V) to ensure a homogeneous composition in around 60 seconds is just above 60 Nm<sup>3</sup>/h.
- The steady-state is reached.

# Next Goals

- Find the minimum flow rate at which a homogeneous steady-state is reached.
- Increase the flow rate to guarantee homogeneity in a fixed (and reasonable) time.

\*\* The flowrate is calculated for a mixture  
50%CO<sub>2</sub> - 50%C<sub>4</sub>F<sub>10</sub>

# Minimum Inlet Velocity

The first step consists in finding which is the minimum inlet velocity to guarantee homogeneity of the composition at the outlet.

To achieve this goal a set of steady-state simulations has been run.

The parameters varying along the different simulations are the inlet velocities.

The following velocities have been tested:

- 2.0 m/s
- 0.5 m/s
- 0.3 m/s
- 0.2 m/s
- 0.1 m/s

$$MFA(\Phi) = \frac{[\sum_{i=1}^N \Phi_i \dot{m}_i]}{[\sum_{i=1}^N \dot{m}_i]}$$

$$AA(\Phi) = \frac{[\sum_{i=1}^N A_i \dot{m}_i]}{[\sum_{i=1}^N A_i]}$$

Used for total quantities  
such as:

- Composition
- Temperature

This is the best averaging  
method when dealing with  
quantities strongly influenced  
by the velocity fields.

Used for static variables  
such as:

- Static Pressure
- Density

- $N$  is the number of discrete segments or elements in the flow.
- $\dot{m}_i$  is the mass flow rate through the  $i$ -th segment.
- $\phi_i$  is the value of the scalar quantity in the  $i$ -th segment.
- $A_i$  is the area of the  $i$ -th segment.

In this case, the scalar  
quantity of interest is the  
molar fraction of CO2!!!

# Key Variables

The key variable to take under control is the molar fraction of CO2.

If we start with a tank full of CO2 and start sending an equimolar mixture, we expect that, at infinite time (steady-state), the composition inside the tank will asymptotically tend to the inlet composition.

We will focus on:

1. Molar composition of CO2 on the symmetry plane.
2. Molar composition of CO2 at the outlet.
3. Mass Flow Averaged molar composition of CO2 through the outlet\*.

Mass Flow Average? Why?

\* The MWA

# STEADY-STATE: 2.0 m/s (63 Nm<sup>3</sup>/h)

Here and in the next slides we report:

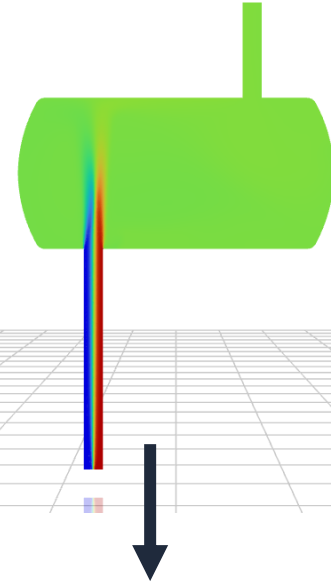

- CO<sub>2</sub> molar fraction (from 0 to 1) along the symmetry plane.
- CO<sub>2</sub> molar fraction (clipped between 0.48 and 0.49) along the outlet pipe's cross-section.

Mole fraction of co2

cont our-xco2-out let - clipp  
-ed

Mole fraction of co2

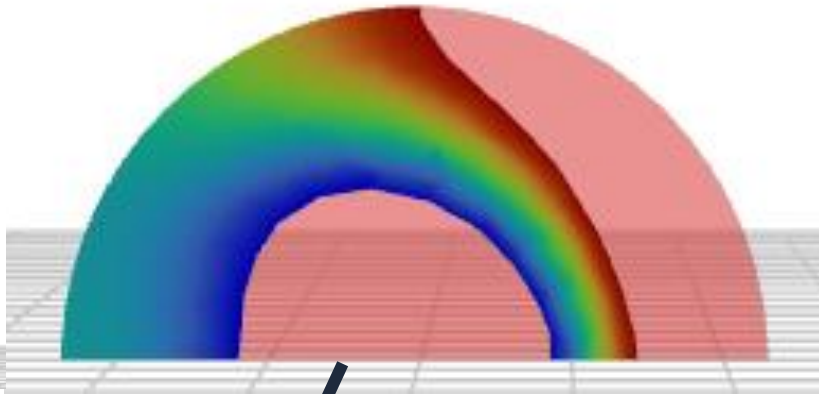

We can notice that both the plots report a homogeneous steady state condition.

Even at the outlet's cross-section the variation is smaller than 1%.

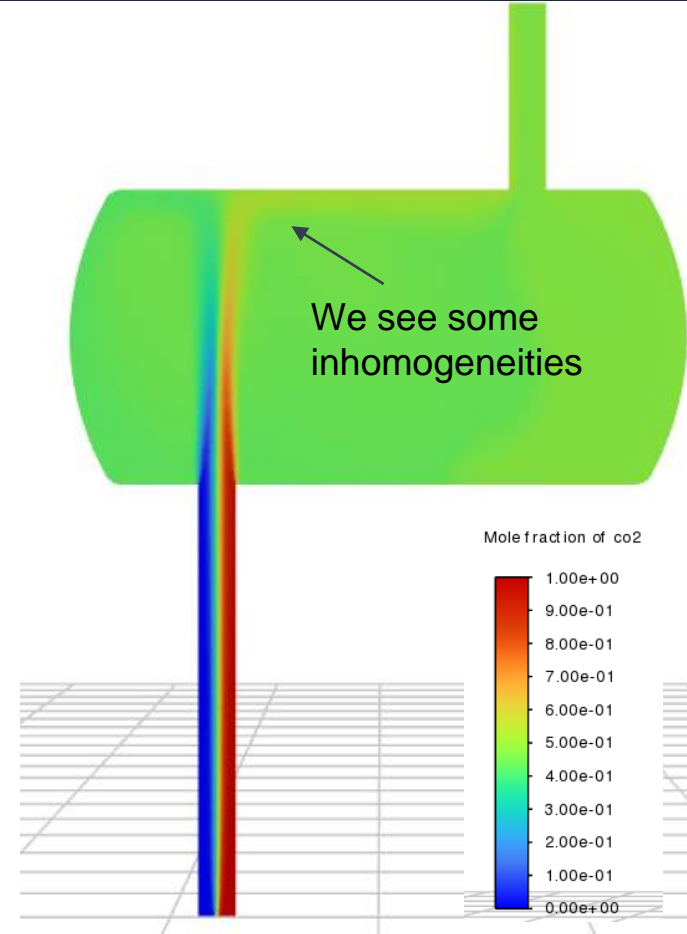

cont our-xco2-out let - clipp

# STEADY-STATE: 0.2 m/s (6 Nm<sup>3</sup>/h)

Mole fraction of co2

Reducing the inlet velocity of one order of magnitude results in a strong inhomogeneity. The empty zones (light red) represent sub-areas where the molar fraction is outside of the desired range.

# STEADY-STATE: 0.5 m/s (16 Nm<sup>3</sup>/h)

Mole fraction of co2

Mole fraction of co2

In this case, when a 4-fold reduction of the inlet velocity has been applied we can't notice huge differences.

This tells us that the solution (minimum velocity) lives in the range between [0.2-0.5] m/s.

# STEADY-STATE: 0.3 m/s (9.5 Nm<sup>3</sup>/h)

The steady-state solution is achieved with an inlet flow rate of 0.3 m/s!

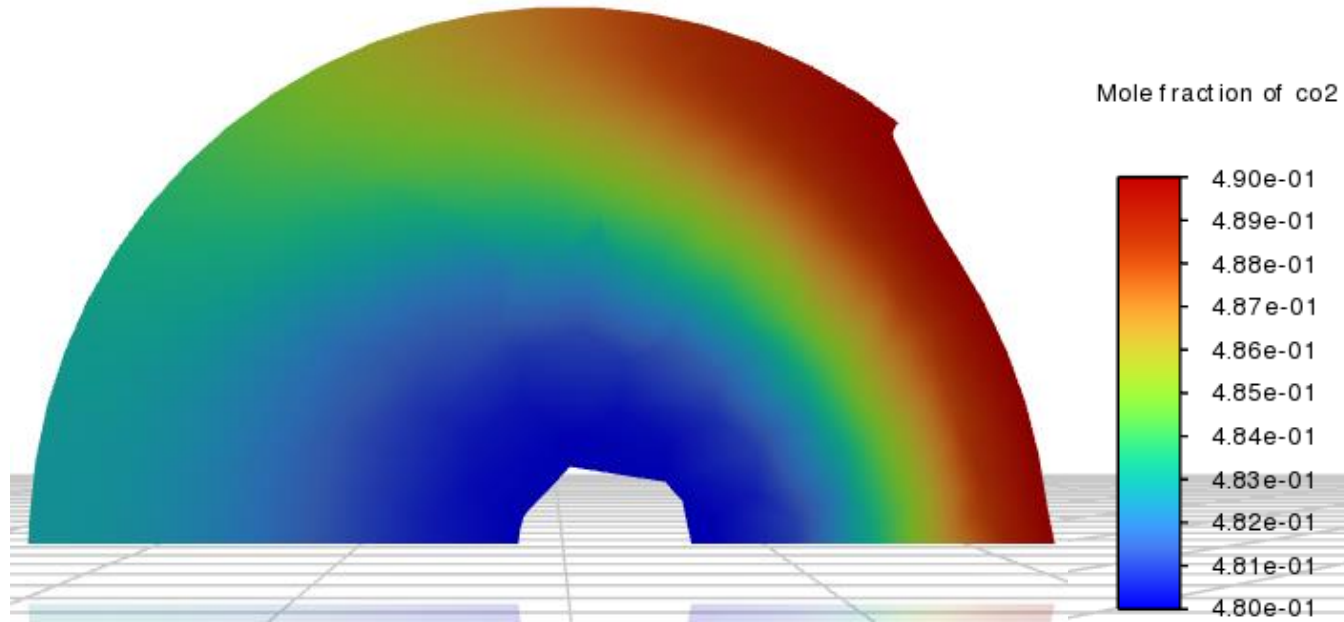

This solution is a trade-off between:

1. The need to minimize the flow rate
2. The necessity to have homogeneous conditions

With respect to the old solution, the flow rate has been reduced almost 7-fold

The occupancy of the surface area of the cross-section where the mole fraction varies by more than 1% is > 95%

# Transient Approach

Once a steady-state solution has been found we look for the following information:

1. What is the characteristic time to reach steady-state conditions? In other words, how long does it take before the variation of composition at the outlet's cross-section is smaller than 1% (given a fixed occupancy)?
2. What is the influence of the velocity (turbulence) on the characteristic time? Is this time just proportional to the volume/flow rate ratio? Is the relationship non-linear?

1. Simulate a steady state and wait for steady-state conditions to be established. In other words, we proceed with the simulation until the Mass Flow Average of the CO<sub>2</sub> mole fraction reaches a constant value (expected to be ~ 0.5).
2. Compare two different transient solutions (at different inlet velocities) to highlight the relationship between the mixture homogeneity and the velocity fields.

**The transient simulation is computationally heavy!**

**The run has been started on Tuesday and is still going!**

**Results will be available (hopefully) next week!**
