# Automatic Optimization of a Parallel-Plate Avalanche Counter with Optical Readout

María Pereira Martínez, Pietro Vischia, Xabier Cid Vidal

2<sup>nd</sup> Computing Challenges Workshop, A Coruña

October 4<sup>th</sup> 2024

# Neutron tomography

Tomography by emission and detection of neutrons for non-destructive tests (NDT).

High penetration, effective for dense materials like metals and alloys.

Metal industry, additive manufacturing, border security...

Frances Yassid  
Ayyad Limonge

Pablo Cabanelas  
Eiras

# What do we want to do?

Optimize the neutron tomography system but... where do we start?

## Optical Parallel-Plate Avalanche Counter

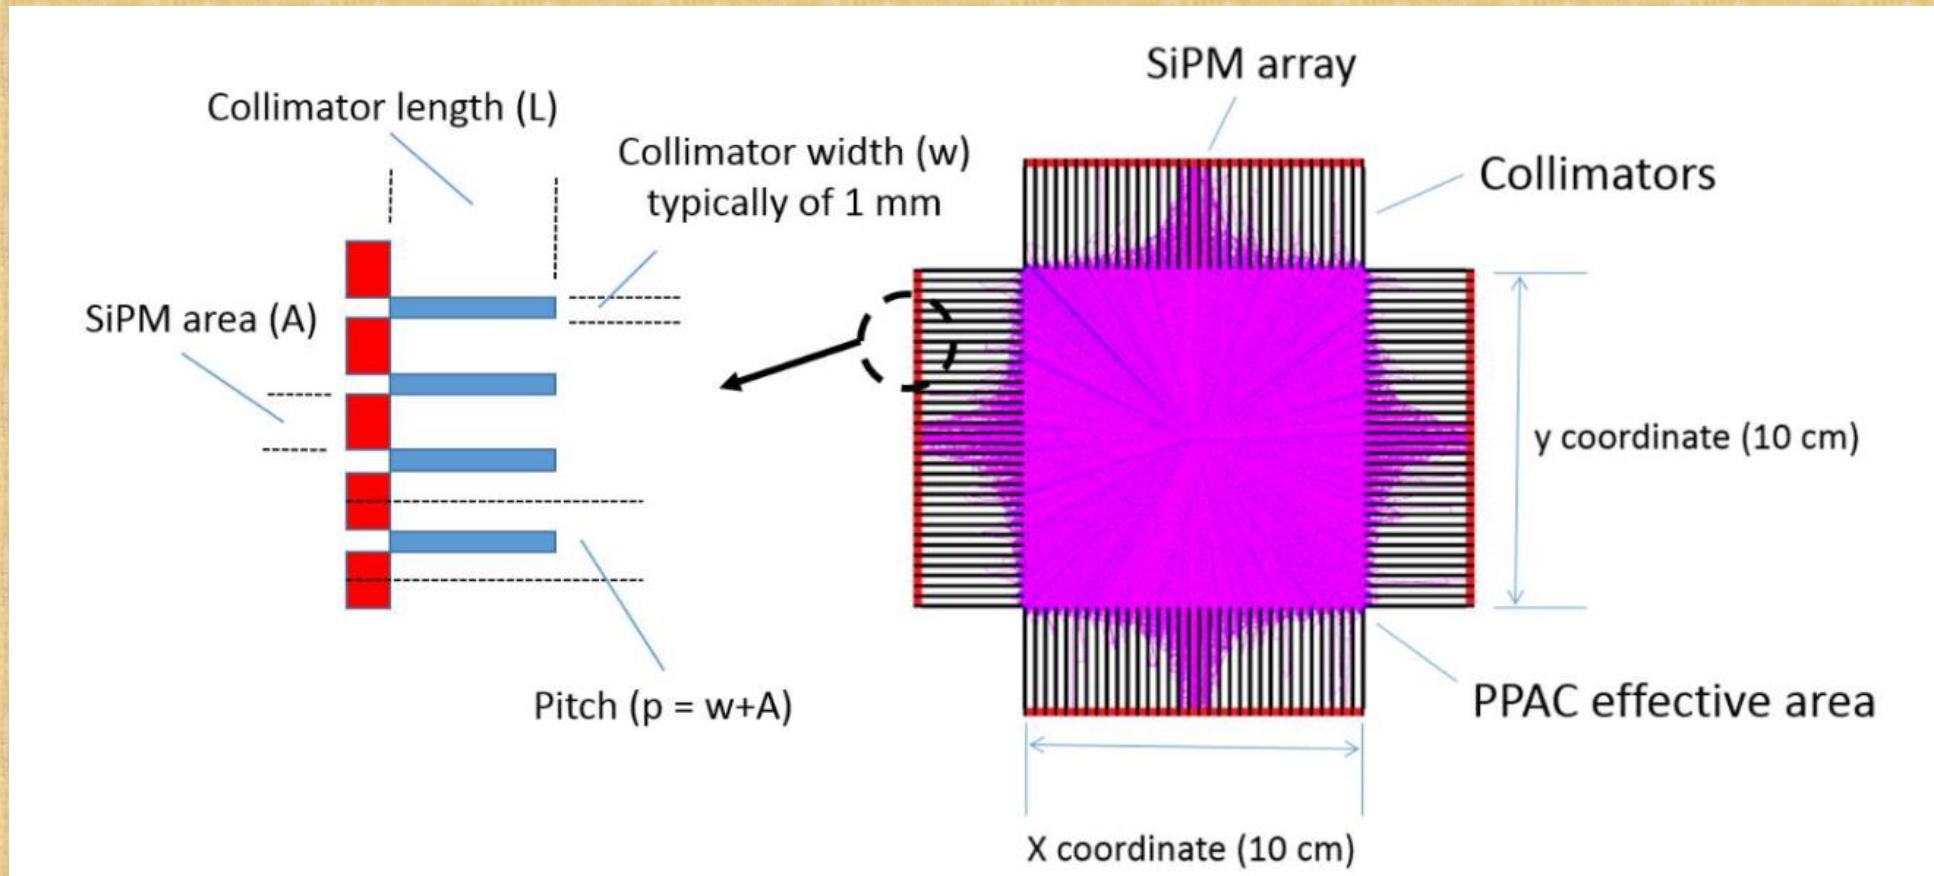

- Parallel-plates filled with a **high electroluminescence yield gas (CF<sub>4</sub>)**.
- Charged particles crossing active volume ionize medium and produce an avalanche.
- Electroluminescence light detected by 4 arrays of small, **collimated silicon photomultipliers (SiPMs)**.

# Optical Parallel Plate Avalanche Counter

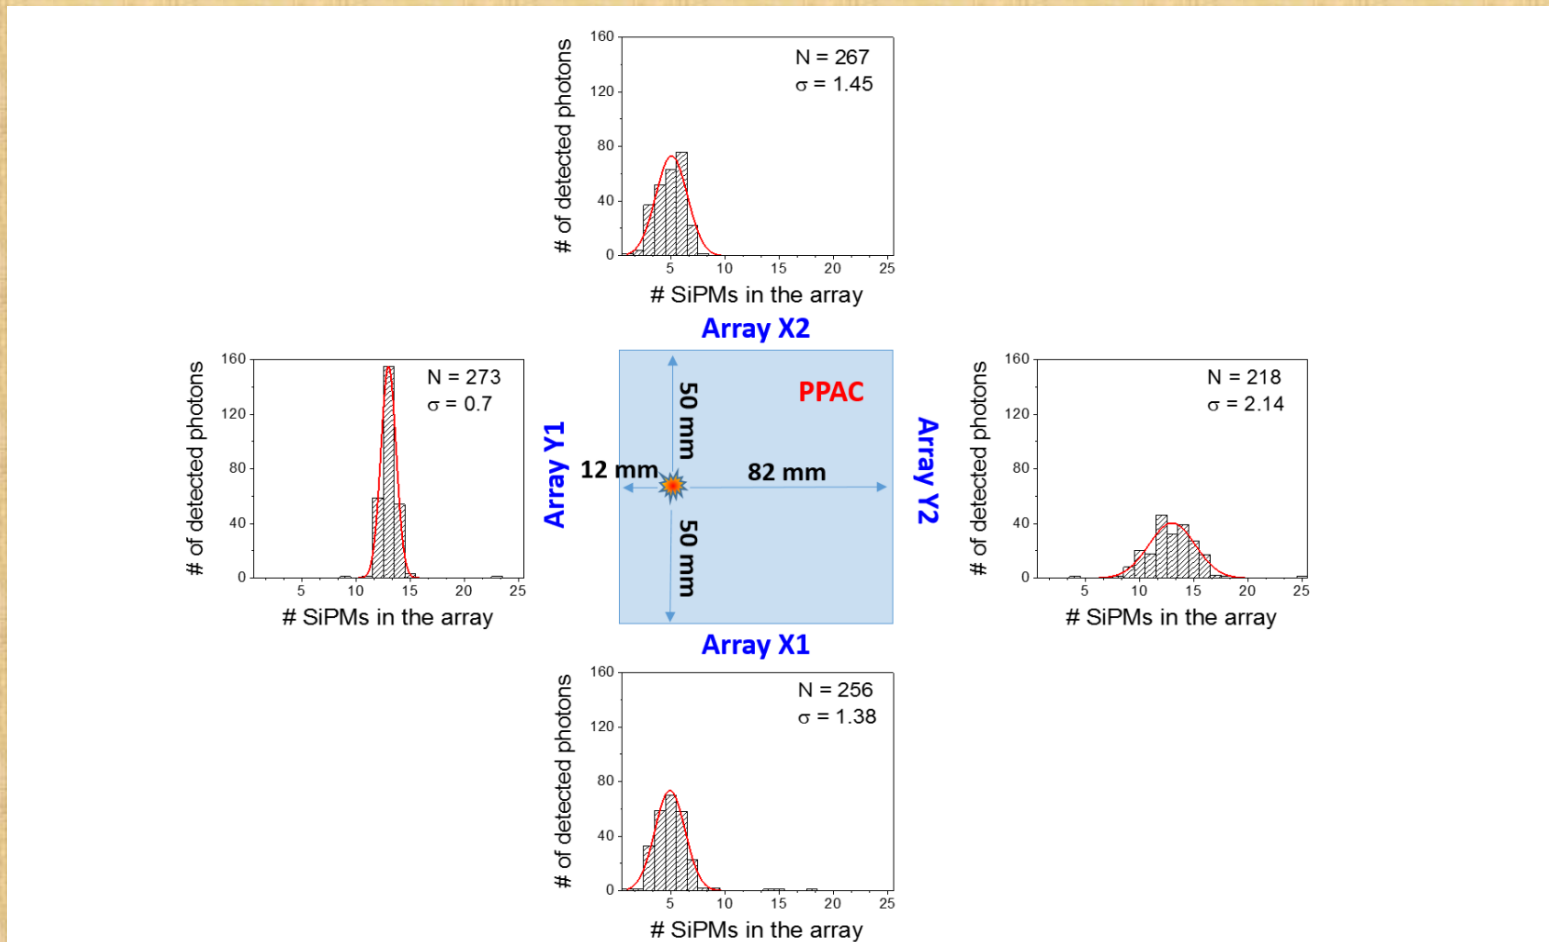

Geant4 model of a  $10 \times 10$  cm<sup>2</sup> O-PPAC, 33 SiPMs per array

Example of an event triggered by an impinging alpha particle:

# Reconstruction of the position

Reconstructed position  $(\hat{x}, \hat{y})$  obtained from the number of photons detected in each SiPM

Weighted average

$$\hat{x} = \frac{\left( \frac{P_{x1} \cdot N_{x1}}{\sigma_{x1}} + \frac{P_{x2} \cdot N_{x2}}{\sigma_{x2}} \right)}{\left( \frac{N_{x1}}{\sigma_{x1}} + \frac{N_{x2}}{\sigma_{x2}} \right)}$$

$$\hat{y} = \frac{\left( \frac{P_{y1} \cdot N_{y1}}{\sigma_{y1}} + \frac{P_{y2} \cdot N_{y2}}{\sigma_{y2}} \right)}{\left( \frac{N_{y1}}{\sigma_{y1}} + \frac{N_{y2}}{\sigma_{y2}} \right)}$$

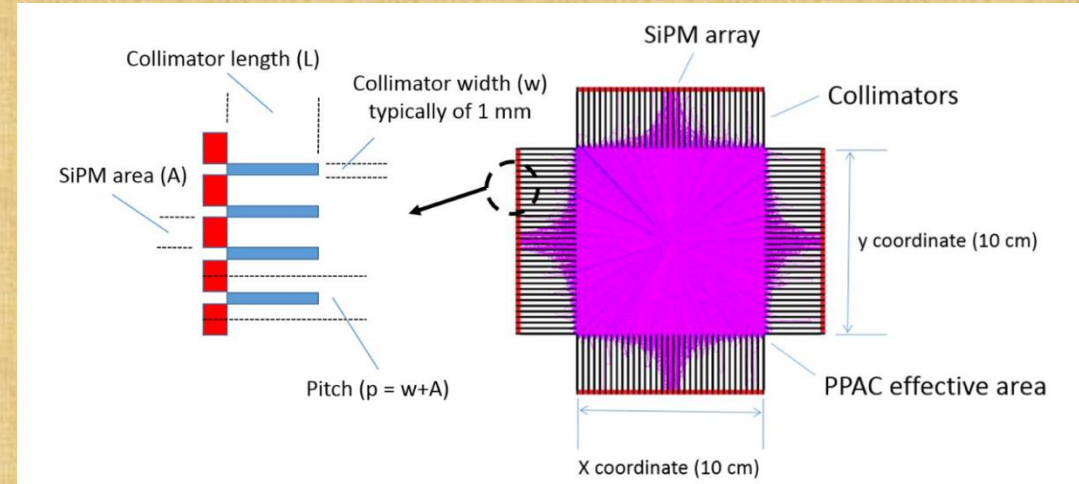

# Parameters of interest

## ▶ Collimator Length ( $L$ ):

- Large  $L$  → better resolution, poor statistics
- Small  $L$  → worse resolution, better statistics

## ▶ Pressure ( $p$ ):

- High pressure → higher photon statistics

## What is the optimal combination of these parameters?

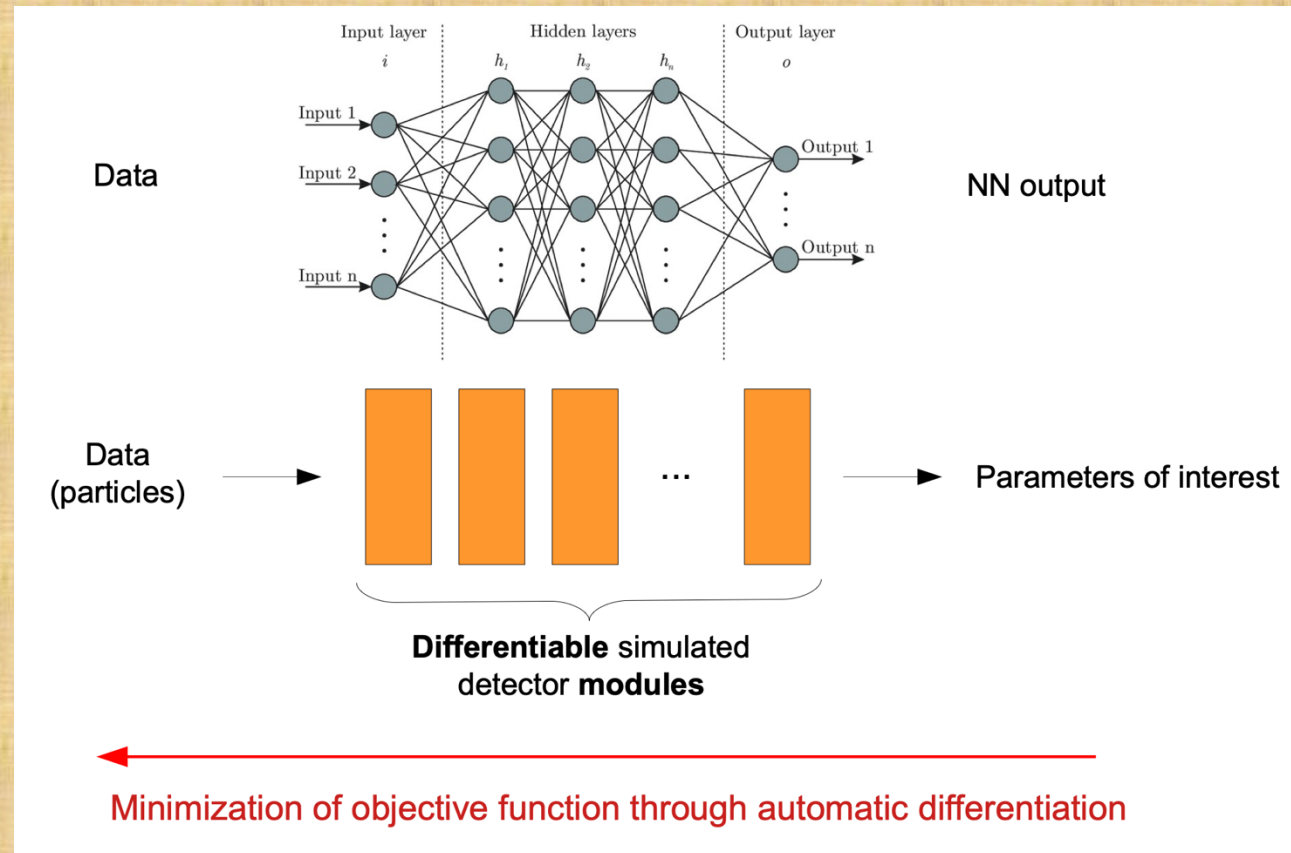

- Traditional approach: simulate the detector for many configurations and test all of them
- New approach: **use differentiable programming and automatic differentiation**

# Differentiable programming for experiment design

Designing experiments is a **challenging task**

- Number of parameters can be too high
- Correlations between parameters can be non trivial
- Traditional approaches are computationally costly

Development of deep learning techniques allows us to take a new approach

NN weights and biases  $\rightarrow$  detector parameters

# Automatic optimization of O-PPAC: Steps

**1. Model detector response as a differentiable function of the parameters**

**2. Set loss function (MSE):**

$$\mathcal{L}(p, L, x, y) = \frac{1}{2} \left[ (x - \hat{x}(p, L, x, y))^2 + (y - \hat{y}(p, L, x, y))^2 \right]$$

\* From step 1

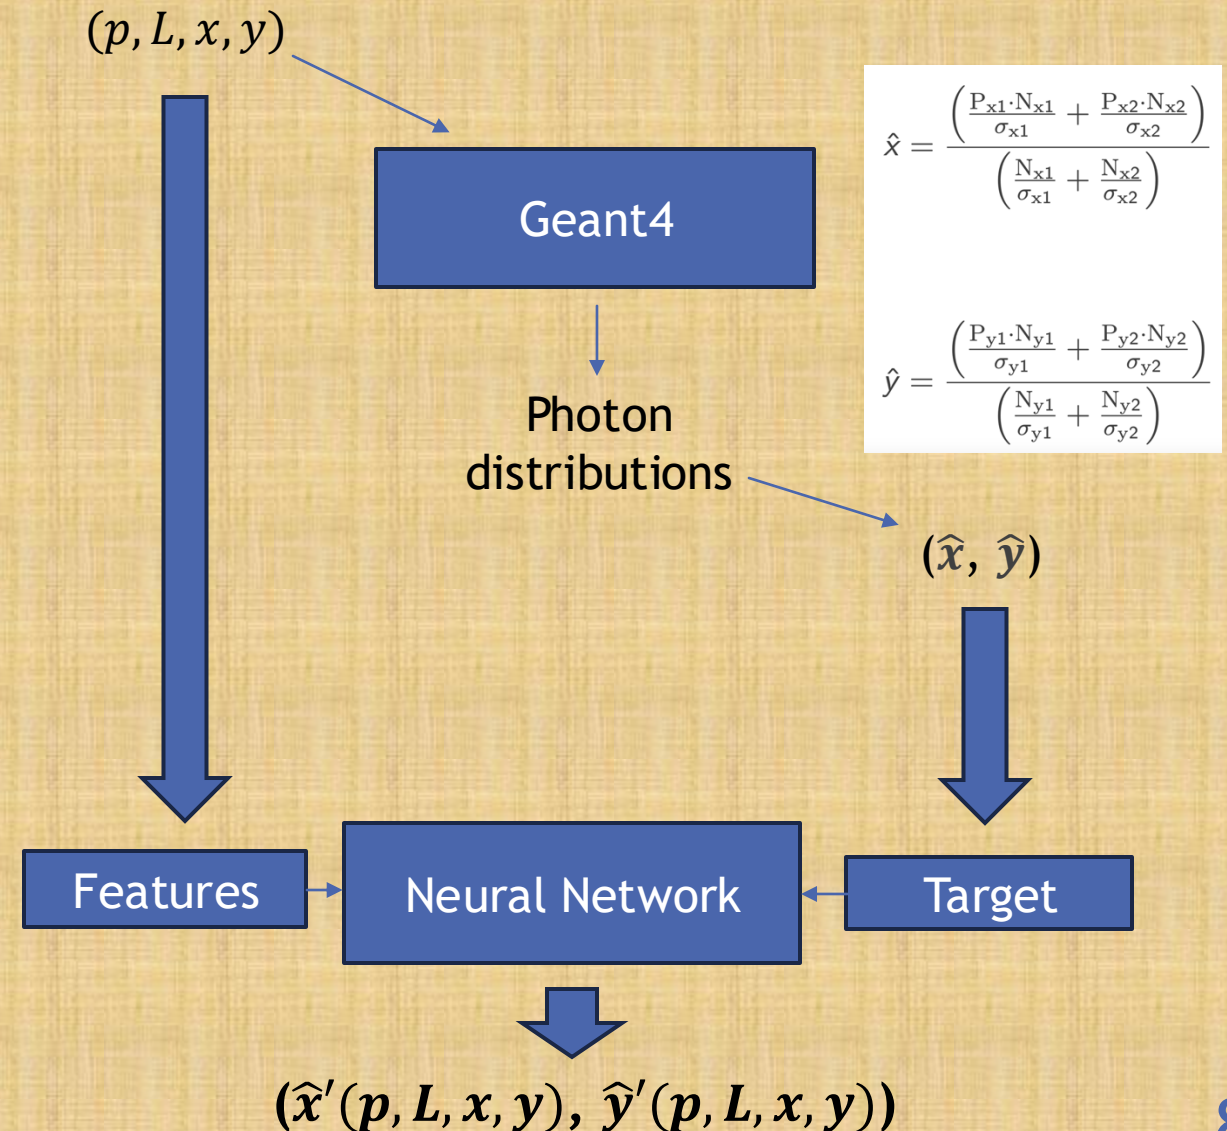

**3. Minimise the loss w.r.t.  $p$  and  $L$  using automatic differentiation**

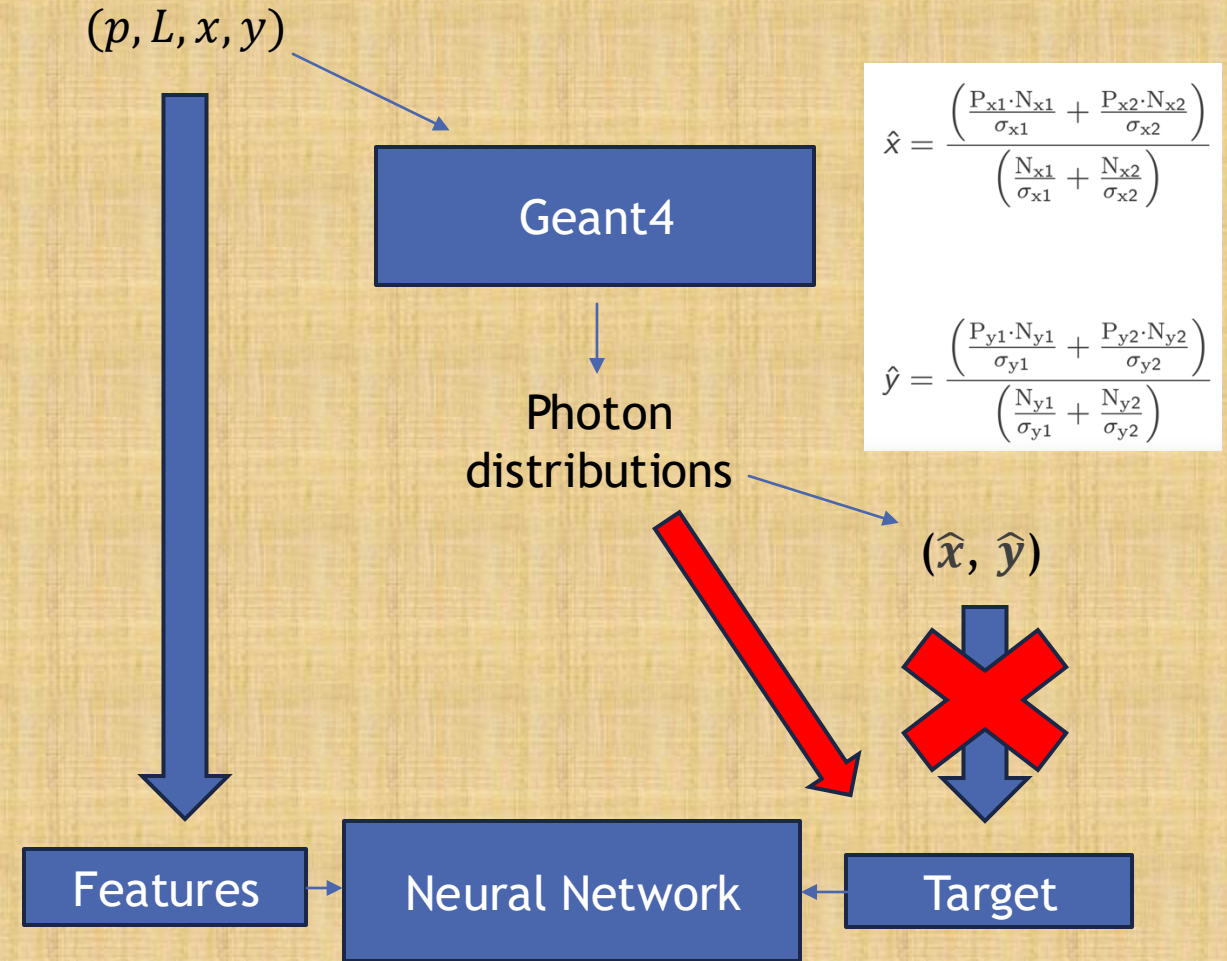

# Automatic optimization of O-PPAC: 1. Surrogate model

- ▶ Geant4 is not differentiable!
- ▶ We trained NN to **predict the reconstructed position as a function of  $(p, L, x, y)$** .
- ▶ Once trained, the NN is much faster than the simulation, inference is done in seconds while simulation takes ~hours.

# Automatic optimization of O-PPAC: Surrogate model

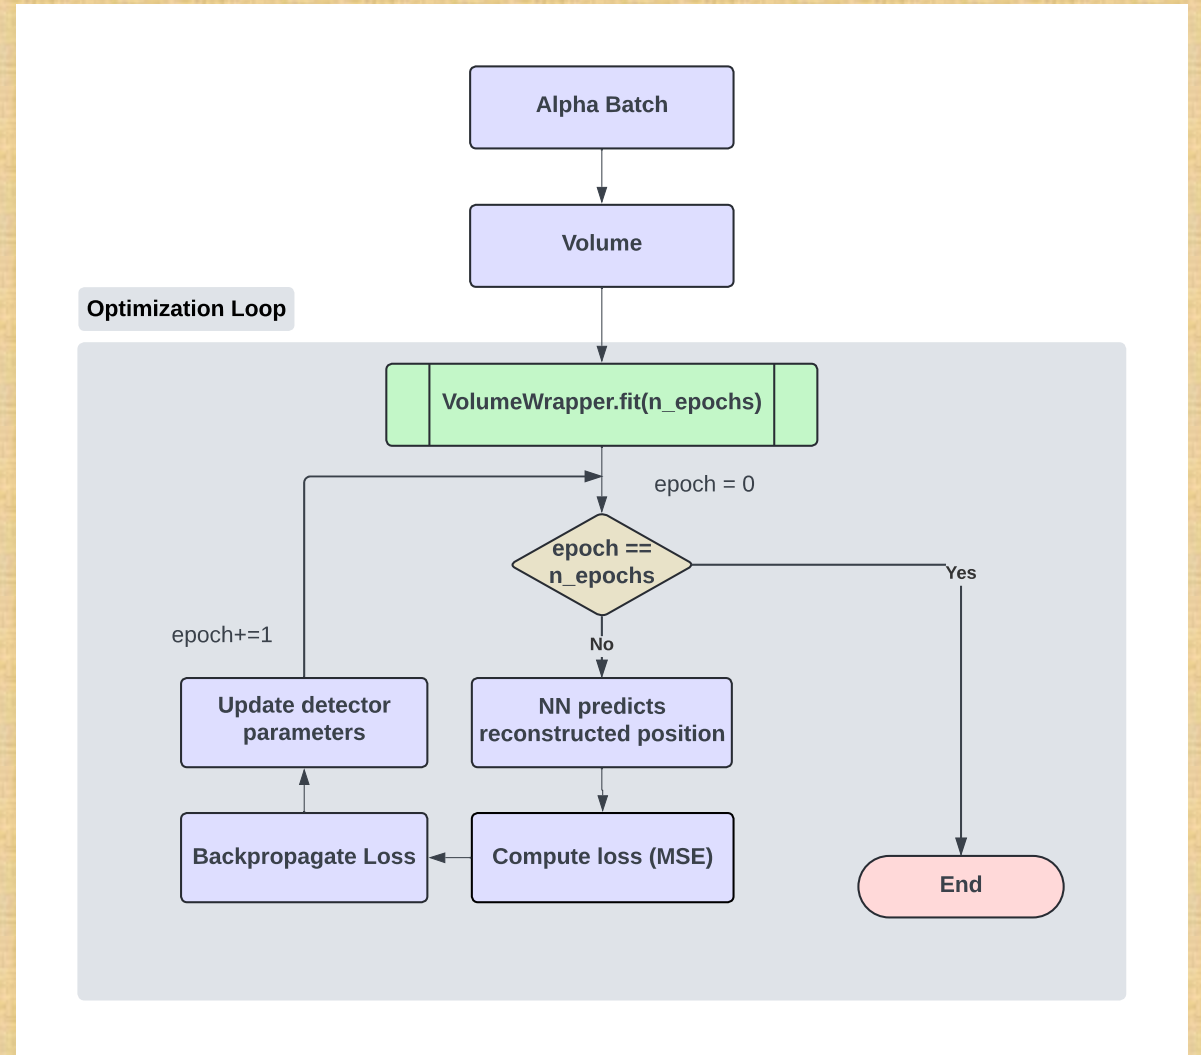

- ▶ Geant4 is not differentiable!
- ▶ We trained NN to **predict the reconstructed position as a function of  $(p, L, x, y)$** .
- ▶ Once trained, the NN is much faster than the simulation, inference is done in seconds while simulation takes ~hours.
- ▶ **Current efforts on including the reconstruction step into the differentiable pipeline**

# Automatic optimization of O-PPAC: Optimization loop

## How it works?

1. Generate random input for the NN.
2. NN predicts the reconstructed position.
3. Evaluate the loss, i.e. the reconstruction error.
4. Backpropagate loss
5. Update  $p, L$  in the direction that minimizes the loss

# Automatic optimization of O-PPAC: Results

Solution remarkably stable **regardless of initial configuration**

# Automatic optimization of O-PPAC: Results

Collimator length result matches the traditional approach: [10.1088/1748-0221/13/10/P10006](https://doi.org/10.1088/1748-0221/13/10/P10006)

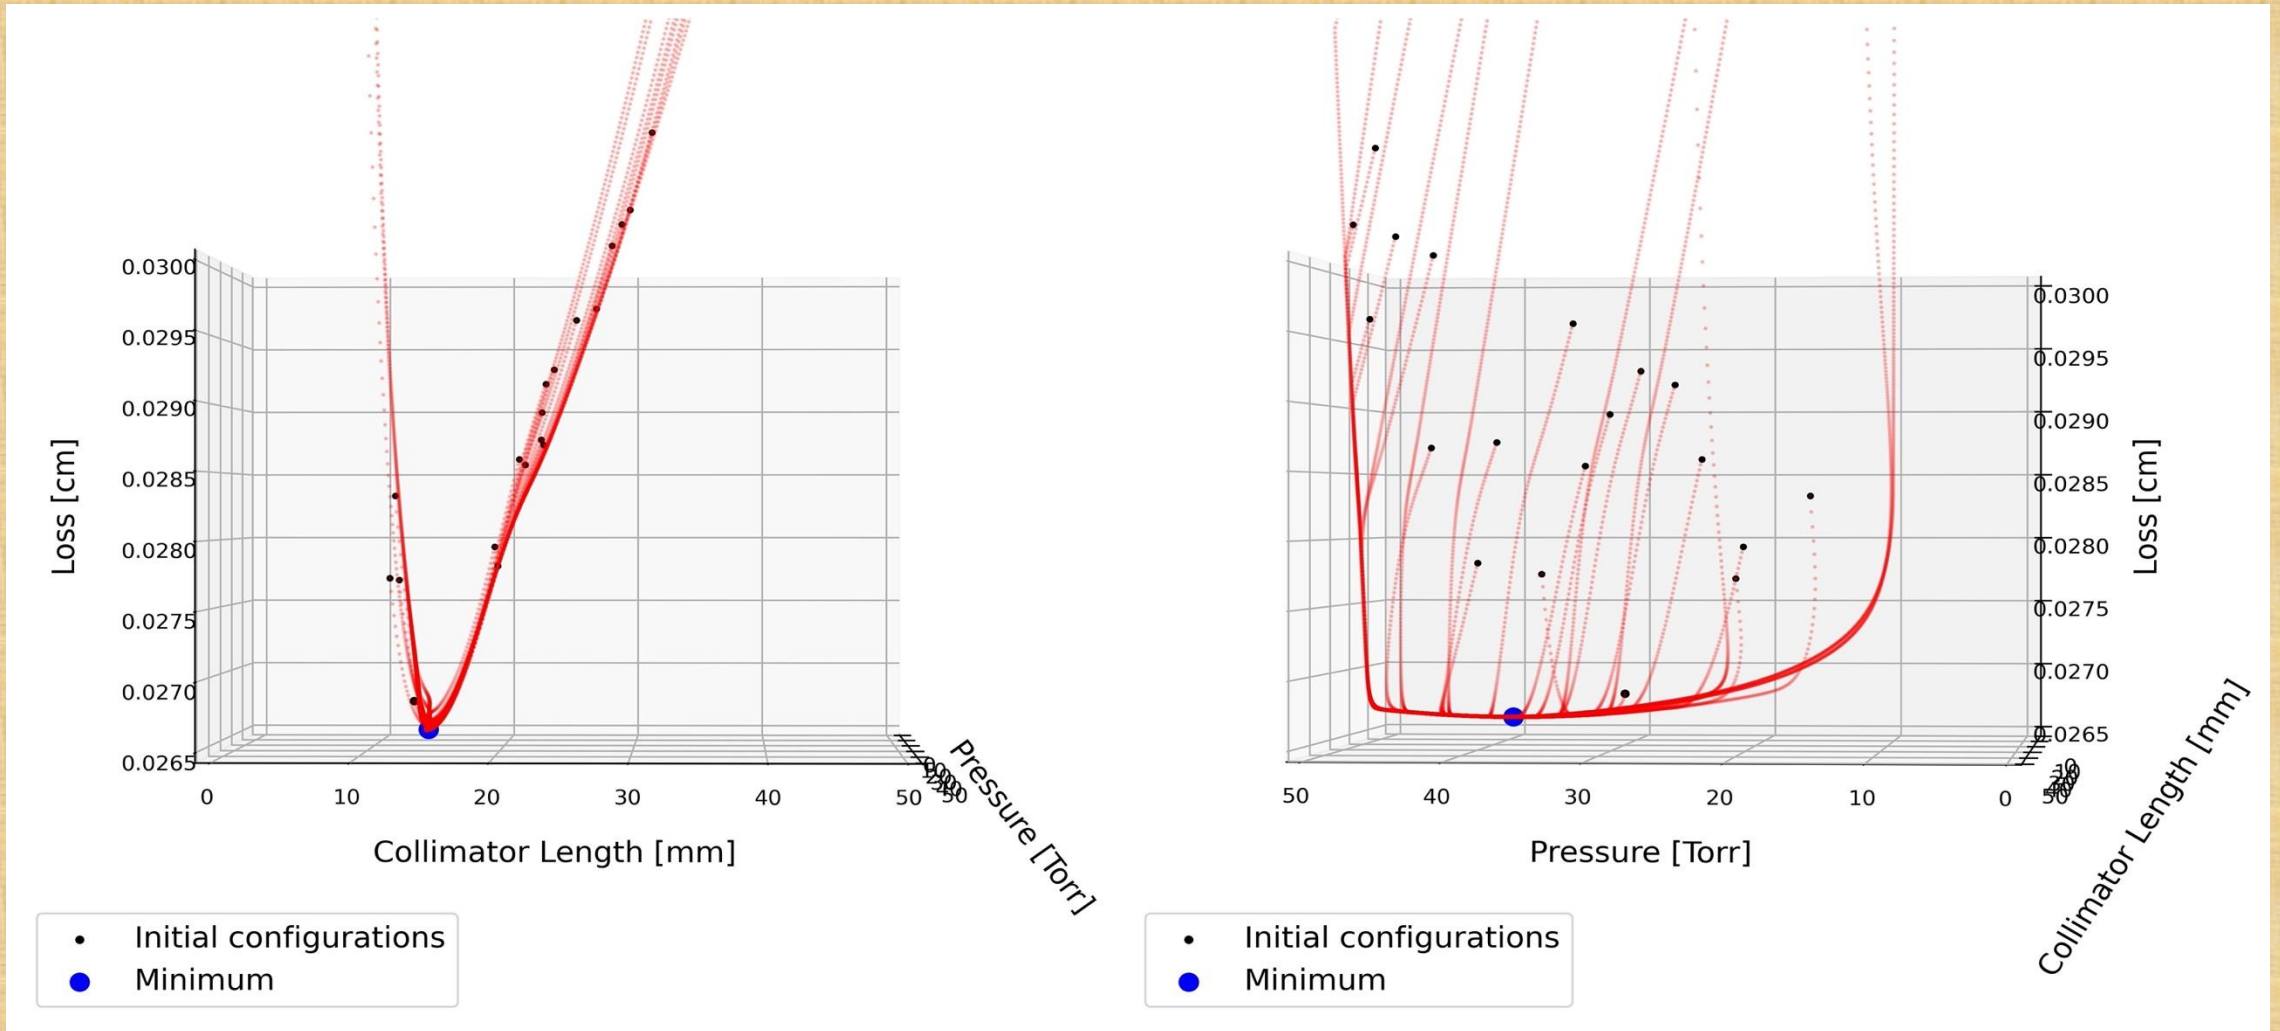

# Automatic optimization of O-PPAC: Results

Pressure has a more complex behaviour

- Higher pressure means more photons
- We would expect the highest value (50 Torr)
- **This is not the case:**
  - Is this an effect of the simulation?
  - Is it an effect of the surrogate model?
  - Further research is needed.

# Automatic optimization of O-PPAC: 3D visualization

# Conclusions

- ▶ We are employing **differentiable programming** and **automatic differentiation** for the optimization of the O-PPAC detector.
- ▶ With this first approach:
  - ▶ Solution for optimal parameters is **stable regardless of the initial configuration**.
  - ▶ Collimator length result **aligns with traditional methods**.

# Next steps

- ▶ Include reconstruction step in the differentiable pipeline
- ▶ Check pressure result
- ▶ Ultimately build the differentiable pipeline for the whole tomography system.
