

# Report for $K_s^0$ analysis method with machine learning

# Introduction

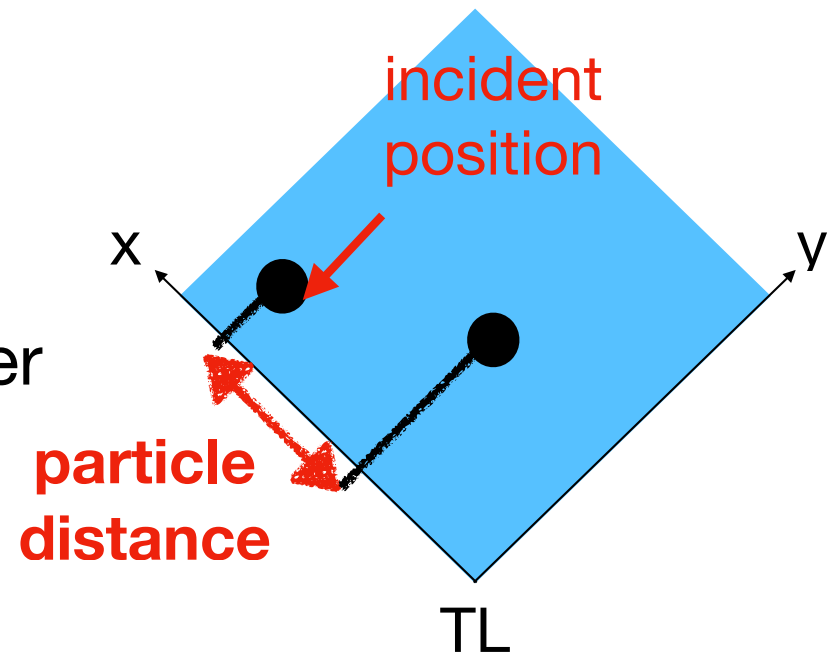

- $K_s^0$  is important to understand the vertical developing for the air shower.
- The decay mode of  $K_s^0$  measured by LHCf detector is following:
  - $K_s^0 \rightarrow 2\pi^0 \rightarrow 4\gamma$  (branching ratio:30.7%)
  - In this case, 4 photon incident on LHCf detector and event criteria is very hard. So events reconstructed of 4 photon is very small with current method.
- I am developing the position reconstruction method of 4photon with using machine learning for  $K_s^0$  analysis and report the status .

# Position reconstruction method

- Position reconstruction method is structured by the following programs.
  - 1. Search number of peak with TSpectrum
  - 2. Fitting using double Lorentzian function corresponding to the number of peak.
- To reconstruct the positions of the four photons, the peaks must be far enough interval to be found by TSpectrum.
- I create each machine learning models for the peak search and the position predict.
  - Verified how accurately independent machine learning models for 1 and 2 can predict

# Position reconstruction method

- Position reconstruction method is structured by the following programs.
  - 1. Search number of peak with TSpectrum
  - 2. Fit to double lorentzian function corresponding number of peak
- I defined the parameter 'particle distance' as shown the particle apart on right fig.
  - Interval of x-axis in calorimeter coordinate at TL

# Gradient Boosted Decision Tree(GBDT)

- GBDT is a kind of machine learning model. It increase accuracy to be structured several Decision Tree not high performance.
- In this work, I used the library XGBoost both peak search and prediction of peak position.
  - For prediction of peak position, I make each model for each peak.

input

number of peak

or

each peak position

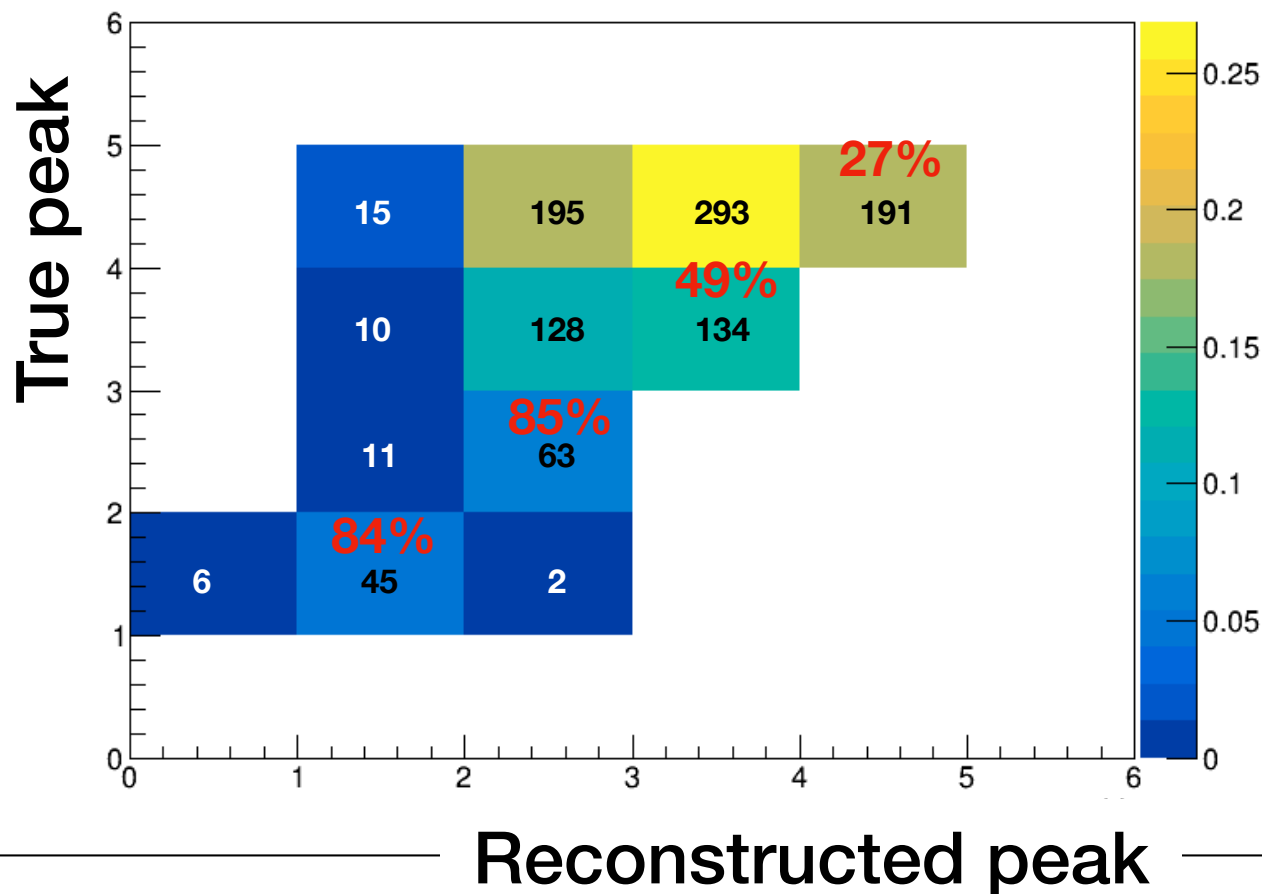

# Number of hit with current method

- true data
  - 4hit 694 event
  - 3hit 272 event
  - 2hit 74 event
  - 1hit 53 event

- Criteria
  - a photon energy  $> 100\text{GeV}$
  - particle distance  $> 3.0\text{mm}$

## True peak vs Reconstructed peak (TL, X)

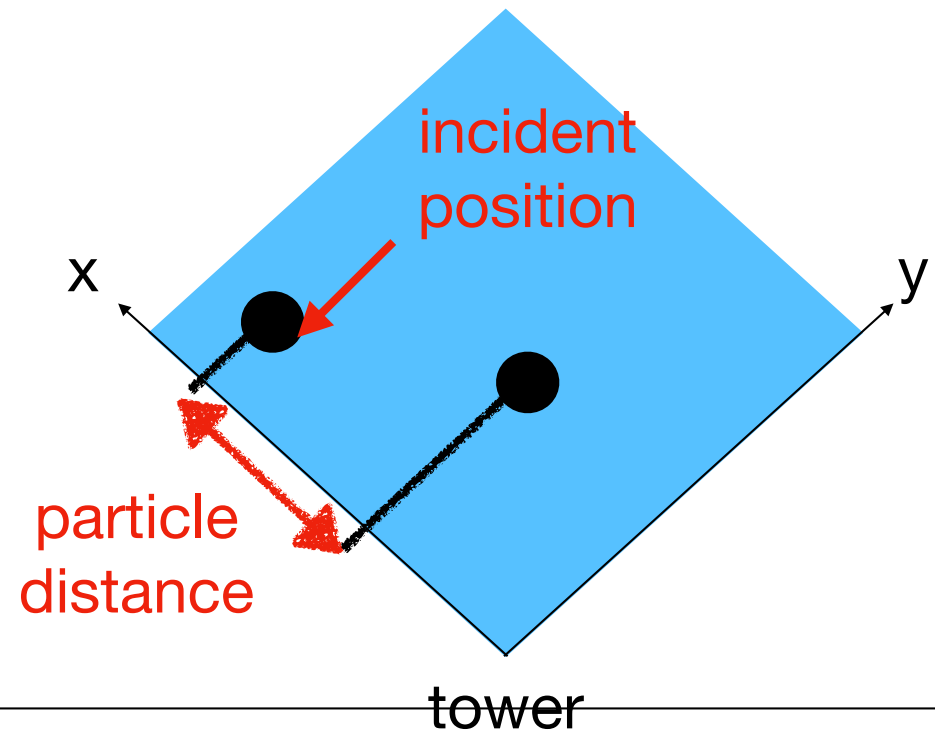

- Many 4hit events are mistaken for 3hit events, but never identify 3hit or 2hit events as 4hit.

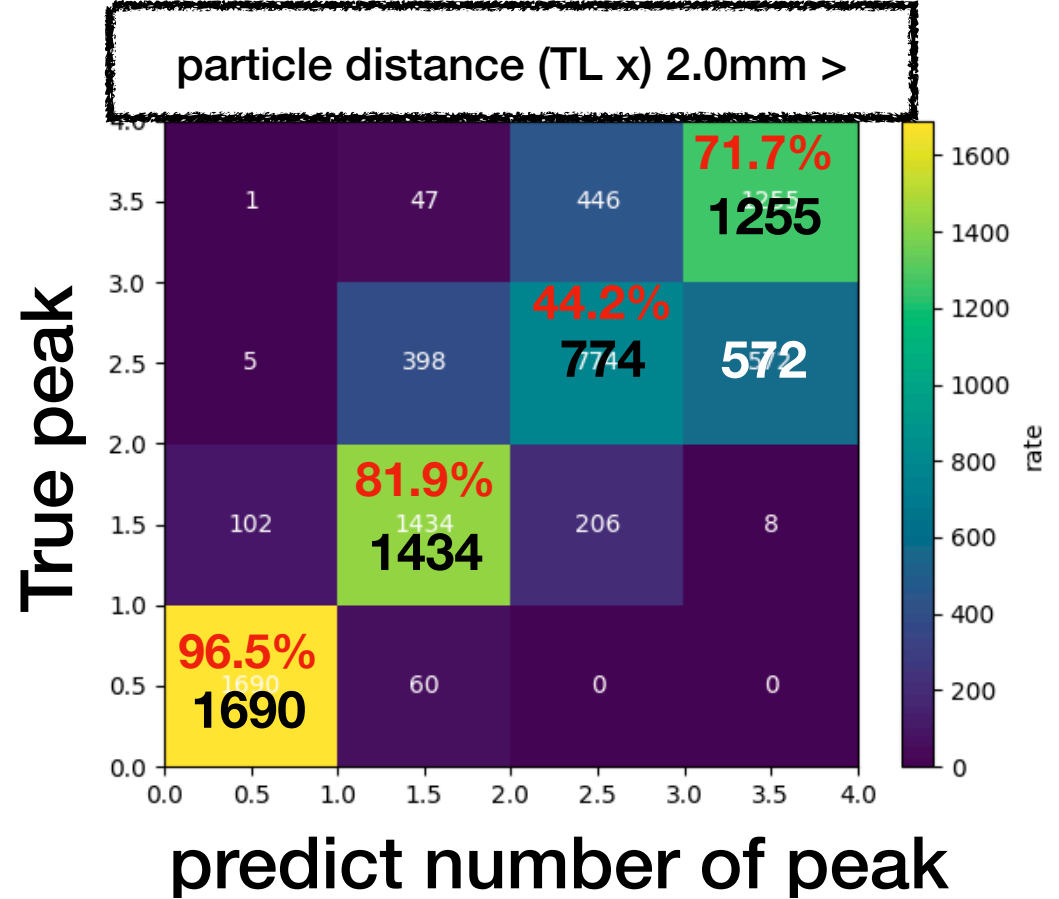

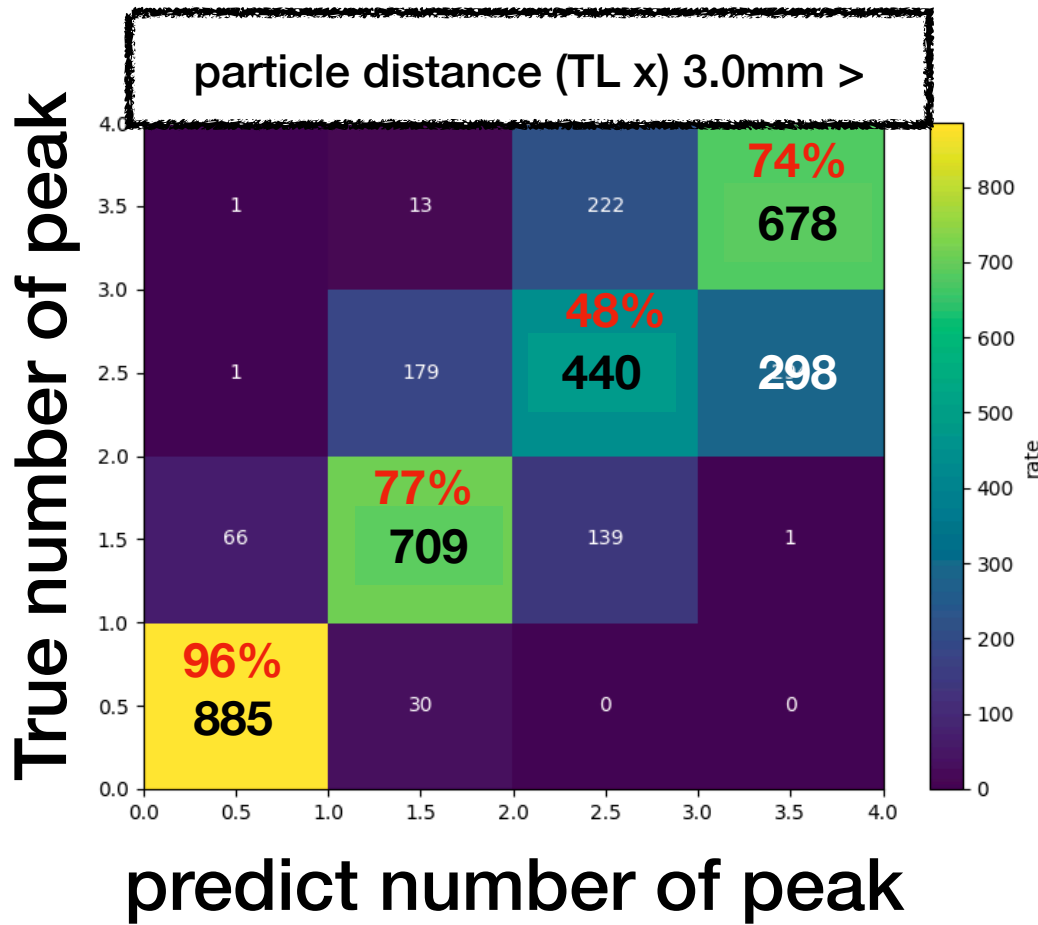

# number of peak with machine learning

- Data set
  - energy deposit on position layer (the 1st & 2nd layer)
  - Large Tower (x axis)
  - one photon energy  $> 100\text{GeV}$
  - particle distance  $> 3\text{mm}(3658)$  ,  $2\text{mm}(6998)$  ,  $1\text{mm}(13624)$

- hyper parameter
  - study rate 0.1
  - max\_tree 4
  - number of study 100

# Predict number of peak (xgboost)

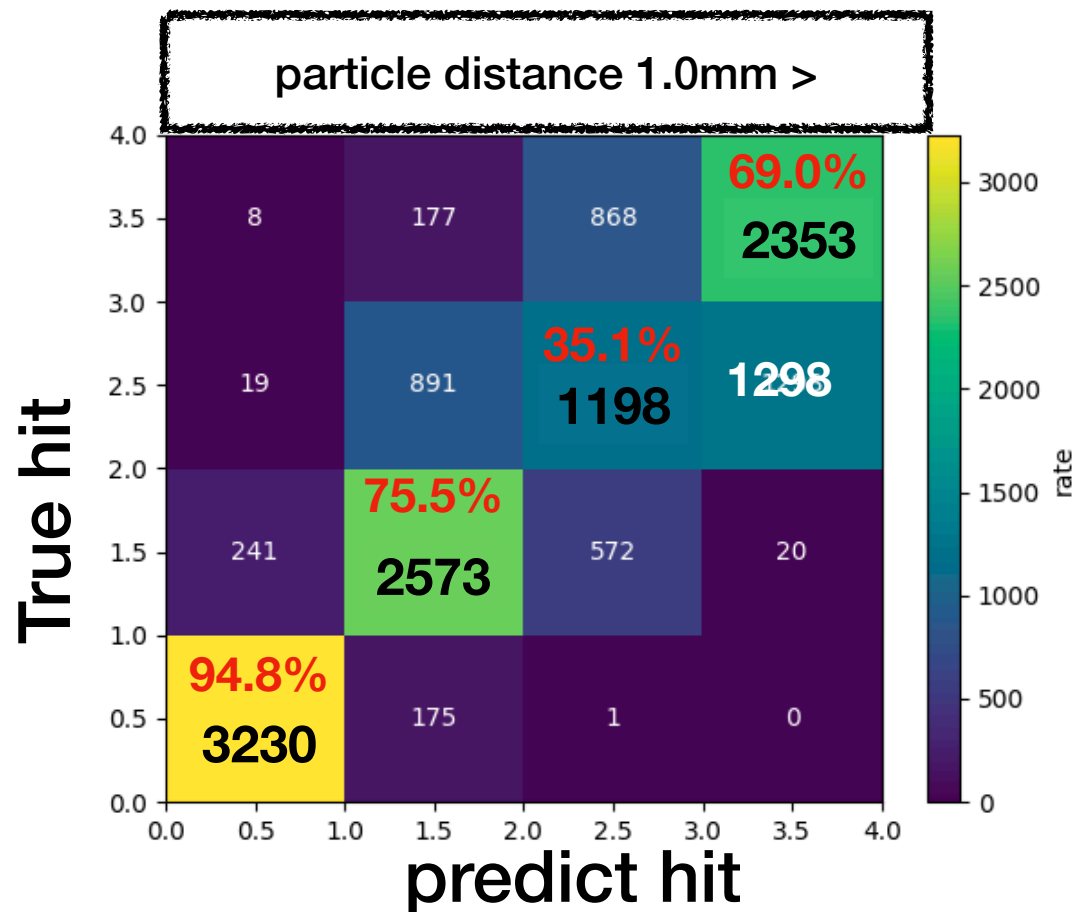

red : rate by bin  
black : events

# Predict number of hit (xgboost)

- Compared with the results of the current reconstruction method, 4hit can be correctly determined even when the particle distance is more than 1 mm.
- Note the appearance of a 3-hit event that is mistaken for a 4-hit event.
  - For right figure, 30% of the events predicted to be 4hit are 3hit events.

red : rate by bin  
black : events

# predict position with machine learning

- Data set
  - Large Tower (x axis)
  - position layer (the 1st & 2nd layer)
  - one photon energy  $> 100\text{GeV}$
  - particle distance  $> 1\text{mm}$

- Instead of predicting four peak locations from a single model, a model was created for each peak.

**I do not optimize the hyper parameter**

peak position

# Predict position result (xgboost)

## 1st peak

Plot of true X vs predicted X for Large Tower, first particle, with XGBoost Fraction

## 2nd peak

Plot of true X vs predicted X for Large Tower, second particle, with XGBoost Fraction

## 3rd peak

Plot of true X vs predicted X for Large Tower, third particle, with XGBoost Fraction

## 4th peak

Plot of true X vs predicted X for Large Tower, fourth particle, with XGBoost Fraction

- Named 1st, 2nd, 3rd, 4th peak in order of energy.

- Predicted peak position by machine learning deviates from baseline as peak height decreases

# Predict position result (reconstruction)

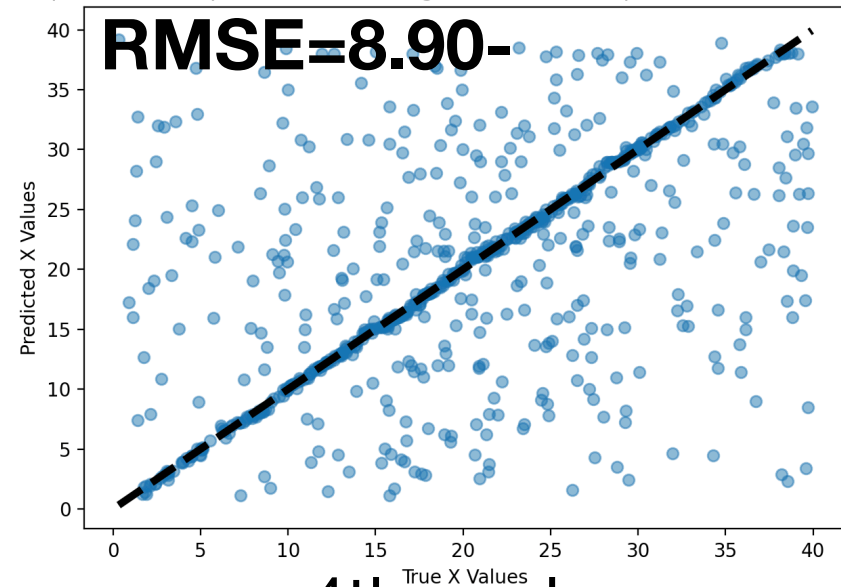

## 1st peak

atter plot true X vs predicted X for Large Tower, first particle, with Baseline

## 2nd peak

ter plot true X vs predicted X for Large Tower, second particle, with Baselin

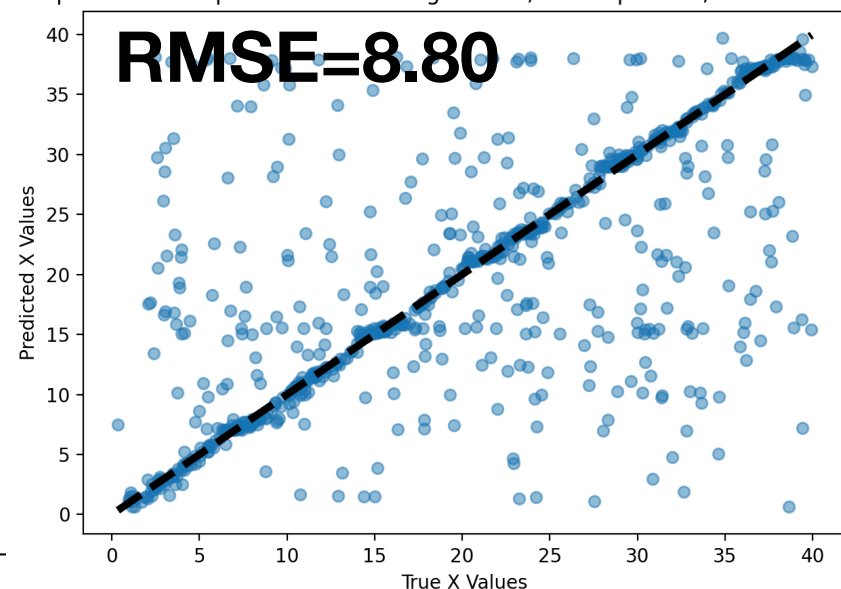

## 3rd peak

atter plot true X vs predicted X for Large Tower, third particle, with Baseline

## 4th peak

tter plot true X vs predicted X for Large Tower, fourth particle, with Baseline

# Conclusion

- In peak search using machine learning, the percentage of correctly judged 4-hit events was 69% even when the particle distance was 1.0 mm.
  - It should be noted that the number of events in which a 3-hit is judged as a 4-hit increased.
- Predicted peak position by machine learning deviates from baseline as peak height decreases
- I think it would be better to use machine learning for peak search algorithm and develop a method to get peak position by fitting.
  - How to remove the result deviating from baseline.
  - How to set initial parameter on Minuit2.
  - How to implement number of peak search method with machine learning in NewLibrary.

# hyper parameter of predict peak position model

## 1st peak

- hyper parameter
  - study rate 0.02
  - lambda 4
  - number of study 800

## 2nd peak

- hyper parameter
  - study rate 0.001
  - lambda 2.4
  - number of study 500

## 3rd peak

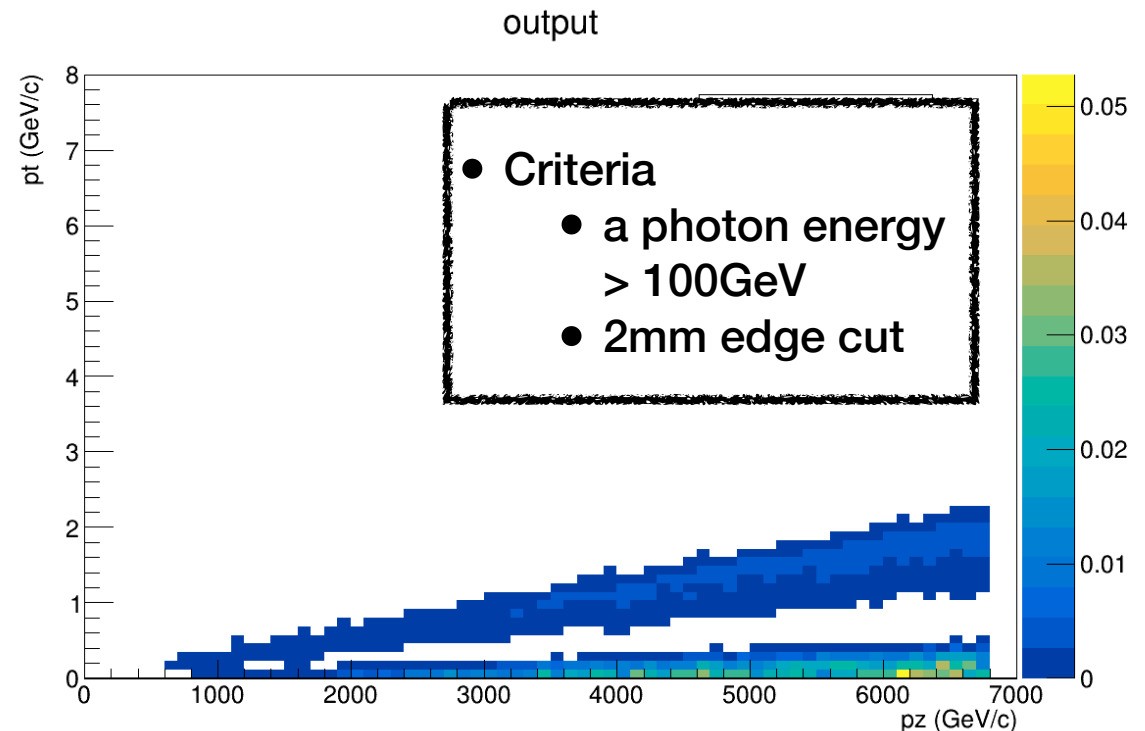

- hyper parameter
  - study rate 0.001
  - lambda 3
  - number of study 400

## 4th peak

- hyper parameter
  - study rate 0.001
  - lambda 2.4
  - number of study 1000

# Issue for $K_s^0$ analysis

- The decay mode of  $K_s^0$  measured by LHCf detector is following:
  - $K_s^0 \rightarrow 2\pi^0 \rightarrow 4\gamma$  (branching ratio:30.7%)
  - In this case, 4 photon incident on LHCf detector and event criteria is very hard. So events reconstructed of 4 photon is very small with current method.
