

BCCM bunch intensity limitation and proposed solution

M. Gasior, T. Levens

Issue

- Issue seen during recent MDs when trying to inject high intensity ($> 2e11$ ppb) trains
- BCCM interlock dumps the beam at injection
- Some time spent checking the RF as de-bunching suspected
- After that, not obvious to OP why...
- **Note: currently no analysis of BCCM PM data – to be implemented!**

Explanation

- BCCM interlocks when the signal level reaches the ADC full scale
 - As we cannot guarantee the protection in this case
- Full scale level is a trade off with noise
 - Higher maximum bunch intensity brings higher noise
- For the initial BCCM system we were **very** concerned about the noise
 - It was not obvious that we could meet the specs
- The run 2 beam spec was understood to be max $1.8e11$ ppb in trains
 - The full-scale was set based on this with some margin
 - Limit is around $\sim 2.2e11$ ppb (absolute maximum) so practically $2.0-2.1e11$ ppb
- Note that, due to the dynamics of the detector used, the limit is higher with larger bunch spacing (and much higher with single bunches)

Solution

- In practice, we have some margin with the noise levels
- So, we can increase full-scale range by installing 2dB attenuators
 - Increases absolute maximum by $\sim 25\%$ from $2.20e11$ to $2.75e11$
- 2dB attenuators ordered and installed on System C (development system, not interlocked) during access on 26/08
- Scaling factors (LSA setting) multiplied by 1.26 to compensate

Proposal

- Install the 2dB attenuators on System A/B before next MD block
- Two options:
 - Single access: changing both systems with single recommissioning
 - Two accesses: only changing 1oo2 with recommissioning for each
- Adjust LSA scaling factors by 2dB
 - Should result in +1% scaling factor compared to now
 - Note: the scaling factors are intentionally set 3-4% above the FBCT to ensure we never underestimate the intensity
- Dates: preferably after 16th September
 - As both myself and Marek will be absent until then
- Further recommissioning steps to do?
 - Or we validate during a normal physics fill at the dump?
