1 st October 2024

# **Outline**

- Introduction
	- Longitudinal Schottky spectrum
	- Transverse Schottky spectrum
- Experimental Schottky spectra from the LHC
	- Longitudinal impedance effect
	- Estimate of the LHC longitudinal impedance
	- Transverse impedance effect
- **Conclusion**

# **Introduction: The Schottky Monitor**

- The Schottky spectrum is based on the measurement of the beam fluctuations in the longitudinal and transverse planes.
- The Schottky spectrum is the **power spectral density** of the beam current in the longitudinal plane and the dipole moment in the transverse planes.
- Important **non-invasive** method for beam diagnostics (emittance, tune, chromaticity, bunch profile, …).
- The Schottky monitor is one of the only instruments with the potential of measuring the LHC chromaticity in a non-invasive way.
- However, **impedance, non-linearities, and other collective effects** can strongly affect the Schottky spectrum, preventing the extraction of beam and machine parameters.

 $\rightarrow$  The distortion caused by impedance can also be used to estimate the impedance itself.

Details of the LHC Schottky system in **M. Betz et al., NIM, vol. 874, pp 113-126, 2017**

# **Longitudinal Schottky Spectrum** (synchronous particle)

# **Longitudinal Schottky Spectrum**

 $\tau_i$  : Time difference between particle  $i$  and the synchronous particle

3. Using the Jacobi Anger relation  $e^{jz\sin\theta} = \sum^{\infty} J_p(z)e^{jp\theta}$  $p=-\infty$ 

 $\rightarrow$  The intensity signal can be written in the following form:

$$
i_i(t) = qf_0 \sum_{n_1, n_2, \dots, n_r}^{\infty} \underbrace{J_p(n\omega_0\widehat{\tau_i})}_{\text{Amplitude}} e^{j \left[\underbrace{(n\omega_0 + p\omega_{s_i})t + p\omega_{s_i}}_{\text{Frequency}}\right]}_{\text{Phase}}
$$

## **Transverse Schottky spectrum**

CÉRN

### **Experimental LHC spectra: Longitudinal Impedance Effects**

- Longitudinal **impedance** significantly affects proton Schottky spectra.
- Spectra of bunches of different intensities (0.5e11 to 2e11 ppb) acquired at injection during MD block 1.

- Impedance can be source of instabilities and can cause intensity limitation. **→ Important to have a good knowledge of the machine impedance.**
- Current LHC **longitudinal impedance model** is a **byproduct of the transverse impedance model. noming the state of the state of the SN. Mounet, PhD thesis,** *The LHC Transverse Coupled-Bunch Instability* **<b>n**
- Could be inaccurate. Main source of longitudinal impedance not necessarily the same as for transverse impedance.
- Model re-evaluation is in progress (RF team, Michail Zampetakis, Ivan Karpov).

Can we extract information about the machine (longitudinal) impedance from the shift of the Schottky satellites?

- 1. Understand how impedance affects the dynamic of the particles (amplitude dependent tune shift).
- 2. How this new dynamic will be reflected in the Schottky spectrum.

#### **Without impedance With impedance**

Longitudinal equation of motion.

**К:** Elliptic integral of the first kind.

Longitudinal equation of motion including forces coming from impedance:

$$
\ddot{\phi} + \Omega_0^2 \sin \phi = \frac{\eta h \omega_0}{p_0} F_{Imp}(t)
$$

$$
\Omega_s(\widehat{\phi}) = \Omega_0 \sqrt{S_1} \left( 1 + \frac{3S_3}{8S_1} \widehat{\phi}^2 \right)
$$

With some approximations, a **relation between synchrotron frequency and oscillation amplitude** can be derived.

Where the  $S_n$  coefficients account for the effect of impedance and are defined from the bunch spectrum  $\widehat{\lambda(\omega)}$  and the impedance function  $Z(\omega)$ .

**Details in: C. Lannoy et al 2024, JINST 19 P03017** 

➔ Impedance is responsible of **an amplitudedependent synchrotron tune shift**.

• The new relation between synchrotron frequency and amplitude can be inserted in the original theoretical expression of the Schottky spectrum:

Synchrotron frequency with impedance

$$
=qf_0\sum_{n,p=-\infty}^{\infty}J_p(n\omega_0\widehat{\tau_i})e^{j\left[(n\omega_0+\widehat{\mu_0}_{s_i})t+p\varphi_{s_i}\right]}\n\qquad \Omega_s(\widehat{\tau})=\Omega_0\sqrt{S_1}\left(1-\frac{3S_3}{8S_1}(h\omega_0\widehat{\tau})^2\right)
$$

• This last expression allows to extend theoretical frameworks such as the Monte Carlo approach or the matrix formalism (K. Lasocha and D. Alves).

 $i_i(t)$ 

**Benchmark of the theory** against macro-particle simulation (PyHEADTAIL).

• Fitting of Schottky spectrum is not trivial as it **depends on many parameters**:

### **Longitudinal band**

- **RF** voltage
- Long. bunch profile
- Long. impedance
- Intensity

#### **Transverse bands**

- **All longitudinal parameters**
- **Betatron tune**
- **Chromaticity**
- Transverse profile
- Transverse impedance
- Lattice non-linearities

• …

 $\rightarrow$  The longitudinal band is easier to fit as it depends on less parameters.

• Fitting of Schottky spectrum is not trivial as it **depends on many parameters**:

**Schottky spectra from MD 11723: Nominal Gaussian bunch, fit with**  $Im(Z_{||})/n = 70$  **m** $\Omega$ 

**Schottky spectra from MD 11723: Nominal Gaussian bunch, fit with**  $Im(Z_{||})/n = 135$  **m** $\Omega$ 

**Schottky spectra from MD 11786: Short q-Gaussian bunch**

Short q-Gaussian bunch:

 $\sigma_{rms} = 0.67 \text{ ns}$ 

$$
\bullet \quad q\ =\ 0.25
$$

• 
$$
N = 4.8e10 \text{ ppb}
$$

**Fitting less obvious** ➔ Neither the full LHC impedance model nor a BB resonator can reproduce closely the measurement.

Better agreement might be obtained by fitting both **shunt impedance** and **cutoff frequency** (study ongoing).

- Overall, best fitting obtained with:  $Im(Z_{||})/n = 135 \text{ mA}$
- Increase of 70% compared with the current longitudinal impedance model:  $Im(Z_{||})/n = 80$  m $\Omega$

N. Mounet, PhD thesis, *The LHC Transverse Coupled-Bunch Instability*  I. Karpov and L. Giacomel IWG talks, https://indico.cern.ch/event/1422663/

• **Still preliminary result,** impact of the cut-off frequency of the broadband model to be analysed.

### **Experimental LHC spectra: Transverse impedance effects**

- Transverse **impedance** significantly affects proton Schottky spectra.
- Spectra of bunches of different intensities (0.1e11 to 2e11 ppb) acquired at injection during MD block 1.

# **Conclusion**

#### **Summary of the talk:**

- Longitudinal impedance.
	- Shift of synchrotron satellites observed experimentally.
	- Theory available allowing fitting of impedance.
	- First measurements seem to indicate an increased impedance w.r.t. current model.
	- Further studies needed to analyse the impact of cut-off frequency.
- Transverse impedance.
	- Tune shift observed in experimental spectra.
	- Theory available for quadrupolar impedance and still to be developed for dipolar impedance.

home.cern

### **Experimental LHC spectra: Transverse impedance effects**

- Transverse **impedance** ➔ Shift and spreading of the central transverse satellites.
- Current development and understanding:
	- **Quadrupolar impedance** ➔ Incoherent tune shift.
		- Theory developed and validated with simulations for a transverse broadband resonator.
		- Expanding theory to arbitrary impedance function.
	- **Dipolar impedance → Coherent tune shift.** 
		- Not clear how coherent tune shift is reflected in the Schottky spectrum, study ongoing.

### **Wake function and impedance**

**Wake function:** integrated force on the test particle.

 $\int \vec{F}_{\text{wake}}(x_s, y_s, s_s, x_t, y_t, s_t) ds_s = -q_s q_t \vec{w}(x_s, x_t, y_s, y_t, z)$ 

**Impedance** : Fourier transform of the wake function

$$
Z_{\parallel}(\omega) = \frac{1}{\beta c} \int_{-\infty}^{\infty} W_{\parallel}(z) e^{\frac{-j\omega z}{\beta c}} dz
$$

$$
\mathcal{L}^{\mathcal{L}}(\mathcal{L}
$$

[1] Wakefields [and Impedances, CAS 2022, K. Li](https://indico.cern.ch/event/1126689/contributions/5068895/attachments/2546263/4384831/Sevrier_Transverse_v01.pdf)

# **Transverse Impedance Effects**

• For a stable beam where the bunch is centered and symmetric around the orbit, the dipolar wake contributions will cancel out.

➔ For similar value of impedances, we except the effects of the dipolar wake to be negligeable compared to the quadrupolar one (on the Schottky spectrum) .

• The quadrupolar wake will contribute to an additional linear focusing (or defocusing) force.

# **Transverse Impedance Effects** (simulation)

We include a **transverse** broad-band resonator in the simulation (with **dipolar and quadrupolar** wakes).

ÉRN

→ Overall shift of the spectrum → Satellites are not simply shifted but their shape are also modified

# **Transverse Impedance Effects (theory vs simulation)**
