

# Beam-Beam Wire Compensator (BBWC) Impedance studies

---

Beam-Beam Wire Compensation Review Meeting  
CERN 14-15 October 2024

Leonardo Sito

A. Bertarelli, F. Carra, L. Gentini, L. Giacomel, B. Salvant, G. Sterbini, C. Zannini

# Outline

- 1. Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
  
- 2. Unshielded BBWC Impedance** ..... Slides 10-12
  
- 3. Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
  
- 4. Interconnections considerations** ..... Slide 25
  
- 5. Conclusions** ..... Slide 27

# Outline

- 1. Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
  
- 2. Unshielded BBWC Impedance** ..... Slides 10-12
  
- 3. Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
  
- 4. Interconnections considerations** ..... Slide 25
  
- 5. Conclusions** ..... Slide 27

# The Beam-Beam Wire Compensator:

**4 BBWC assemblies** (1 per side of IP1 and IP5)

**2 beam lines** per assembly

**3 BBWC modules** per beam line

---

**Tot: 12 BBWC modules per beam**

The impedance study focuses on a **single module**:

Copper structure

# The Beam-Beam Wire Compensator:

4 BBWC **assemblies** (1 per side of IP1 and IP5)

2 **beam lines** per assembly

3 **BBWC modules** per beam line

---

Tot: 12 BBWC modules per beam

The impedance study focuses on a **single module**:

- 1mm Diameter
- 1m Effective length
- 150A/m DC current

**Aluminum Nitride** support:

- Support mechanically the wire.
- Enables better heat dissipation.

# The Beam-Beam Wire Compensator:

BBWC **electromagnetic model** keeps all **significant features** of the mechanical one:

**Integration** with other modules:

1. No stainless-steel **flanges**.
2. No **interconnecting pipes** with other modules.

**Single module:**

1. No stainless-steel **bolts**.
2. Commercial Feedthrough replaced by a **coaxial structure**.

The **BBWC module** can **move** in respect beam.

(Span of movement:  $\pm 12.5$  mm)

- **32.5 mm** → Fully out position
- **7.5 mm** → Operation (end of levelling)
- **5 mm** → Very conservative situation

Some **considerations** on **interconnections** will be given at the end

# Beam-coupling impedance study

**Particle bunch** travels in an accelerator device → **Electromagnetic wake fields**

- The wake fields **dissipate power** (Beam-Induced Heating).
- The wake fields can **trigger instabilities**.

To quantify the wake fields' effects → **Beam-coupling impedance**: frequency dependent complex vector ( $Z$ ) quantity.

Impedance → 3D computation tools (CST®)

# Beam-coupling impedance study

Two figures of merit:

➤ **Stability** (longitudinal) ↔ Low-frequency **effective longitudinal impedance**  $\frac{Im(Z_z)}{n}$ , with  $n = \frac{f}{f_0}$

➤ **Power** deposition (On the **whole device**) ↔  $\Delta W = 2(f_0 e N_{beam})^2 \sum_{p=0}^{\infty} (|\Lambda(p\omega_0)|^2 Re[Z_z(p\omega_0)])$

Computed with **HL beam properties**:

- $N_{beam} = 2748$  (bunches)  $\times$   $2.3e11$  ppb
- Bunch shape: q-Gaussian ( $q=3/5$ ), 1 ns bunch length

LHC budget: ~ **90 mΩ**

Power dissipated by the wire in DC is **2.1 kW**

Significantly decayed after 2 GHz

Also a **comment** on **transverse impedance** contribution will be given.

$N_{beam}$ : number of particles in the beam  
 $f_0$ : beam revolution frequency  
 $\Lambda(p\omega_0)$ : normalized beam spectrum

# Outline

- 1. **Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
  
- 2. **Unshielded BBWC Impedance** ..... Slides 10-12
  
- 3. **Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
  
- 4. **Interconnections considerations** ..... Slide 25
  
- 5. **Conclusions** ..... Slide 27

# Unshielded BBWC module

Surface current distribution in time:

Created using  
SIMULINK CST Studio Suite®

Current in the wire in time:

FFT

Distance wire-beam

- Several **resonances** below 2 GHz
  - **Slope** in the  $\text{Im}(Z_z)$

**Increasing** when getting **closer** to the beam

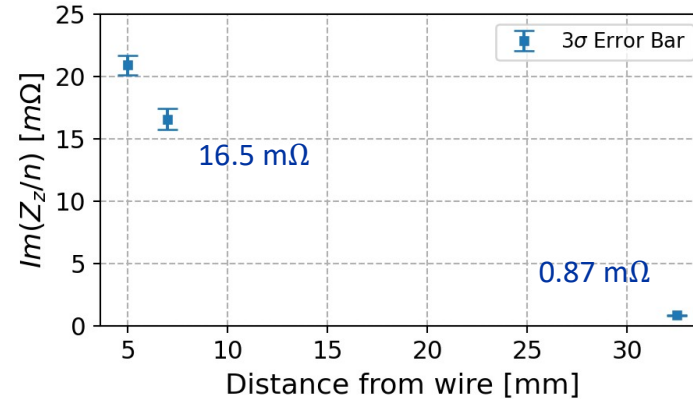

Good understanding of this behavior:  
resonances due to **multiple** current **reflections**  
**along the wire**

# Unshielded BBWC module

Longitudinal Effective Impedance of all **12 modules** per beam

LHC budget  $\frac{Im(Z_z)}{n} \sim 90 \text{ m}\Omega$

DC dissipated power: **2.1 kW**

At **7.5 mm** from the beam:

- Around **20%** of the total budget of **Longitudinal Effective Impedance**
- Around **25%** of the **power dissipated in DC**

Power deposition on a **single module**

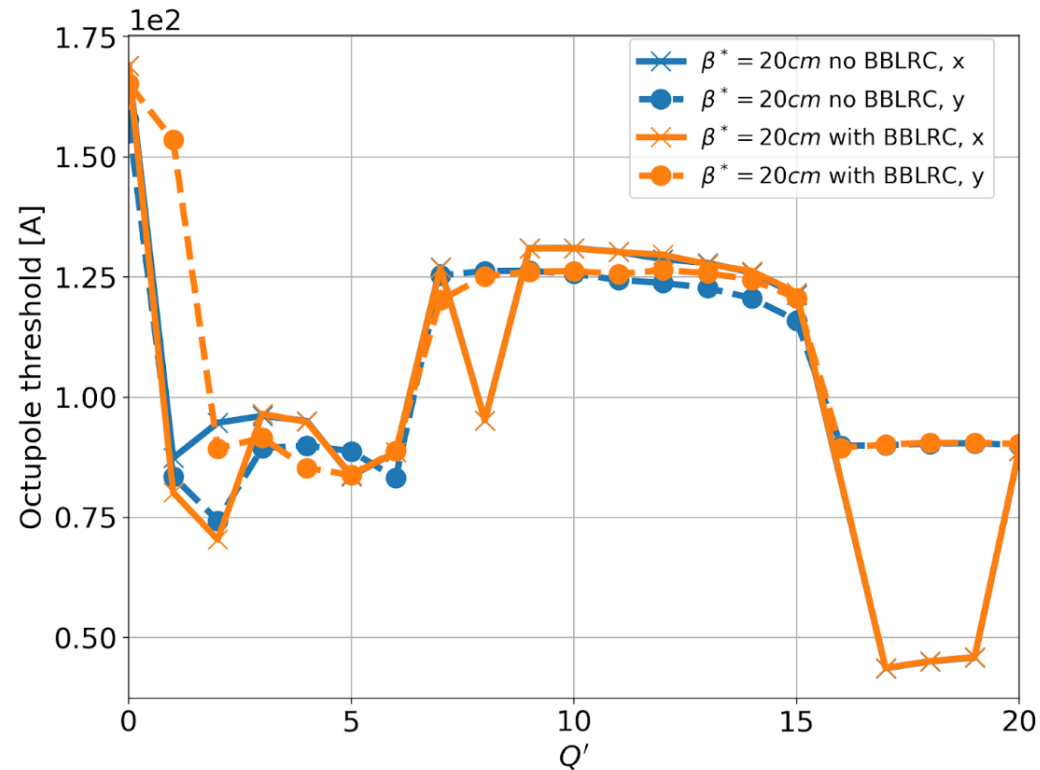

**Impedance contributions are significant**, but **no showstopper is identified** provided impedance minimization iterations in the design.

# Unshielded BBWC module

We compute the **octupole threshold with BBLRC** to check **the impact of the HOMs on beam stability**

B1, positive oct. polarity,  $\tau_b = 1.2$  ns,  $N_b = 2.3e+11$ ,  $M = 3564$ , damp=0.01

Device in parking, end of levelling.

The increase of the stability threshold is well below 10A for  $Q' > 10$ .

# Outline

- 1. **Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
  
- 2. **Unshielded BBWC Impedance** ..... Slides 10-12
  
- 3. **Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
  
- 4. **Interconnections considerations** ..... Slide 25
  
- 5. **Conclusions** ..... Slide 27

# Impedance optimization options

External

Internal shield

**Option A: RF load**

- No modification to the module
- External circuit at wires' termination

**Option B: Elliptical Shield**

- Elliptical pipe as shield
  - Thin window
  - Tapering

**Option C: Box Shield**

- Box on top of wire and Aluminum Nitride support

# Impedance optimization options

External

Internal shield

## Option A: RF load

- No modification to the module
- External circuit at wires' termination

## Option B: Elliptical Shield

- Elliptical pipe as shield
  - Thin window
  - Tapering

## Option C: Box Shield

- Box on top of wire and Aluminum Nitride support

# Option A: RF load

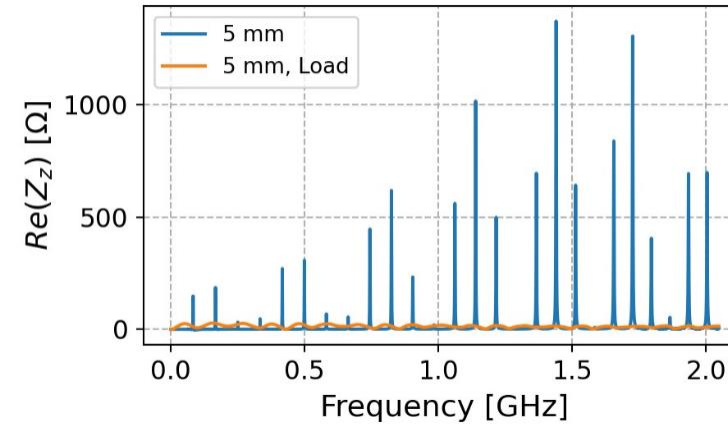

Driving away RF power from the wire to an external circuit, outside of the vacuum chamber.

Idea tested in simulations with a **perfect load**

=

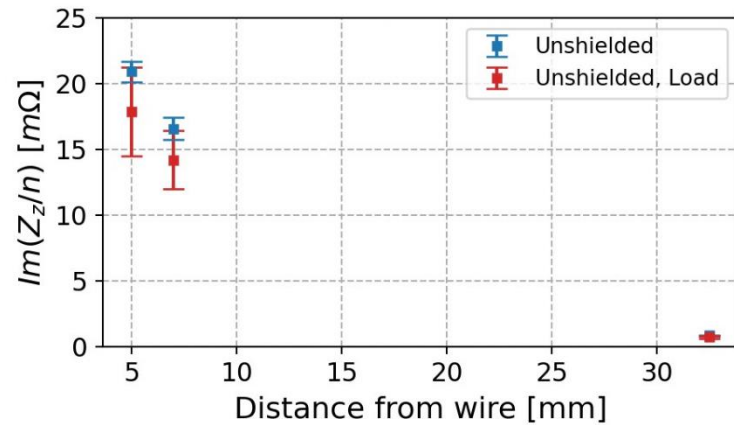

- **Total absorption** of input RF power
- **Minimized reflections** at the termination of the wire

**Strong attenuation of all resonances**

# Option A: RF load

- **No** significant **impact** in terms of **effective impedance**
- **Worse** in terms of **power loss**

➤ **Not a feasible solution** in terms of minimization of **impedance** contributions.

➤ **RF load** at the termination of the wire should be considered for **protection of the power converters** driving the DC current in the wires.

# Impedance optimization options

External

Internal shield

Option A: RF load

- No modification to the module
- External circuit at wires' termination

Option B: Elliptical Shield

- Elliptical pipe as shield
  - Thin window
  - Tapering

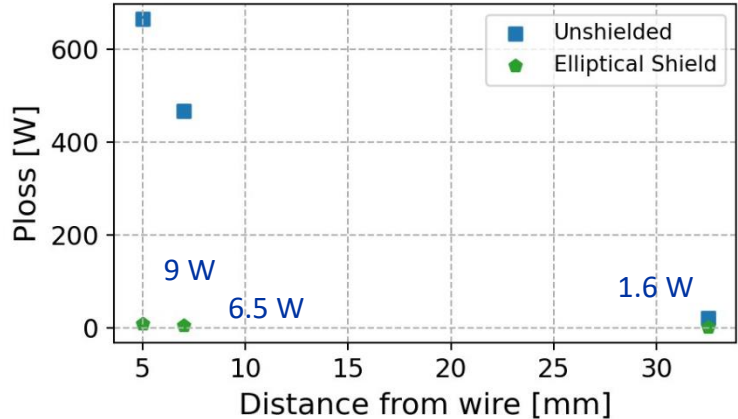

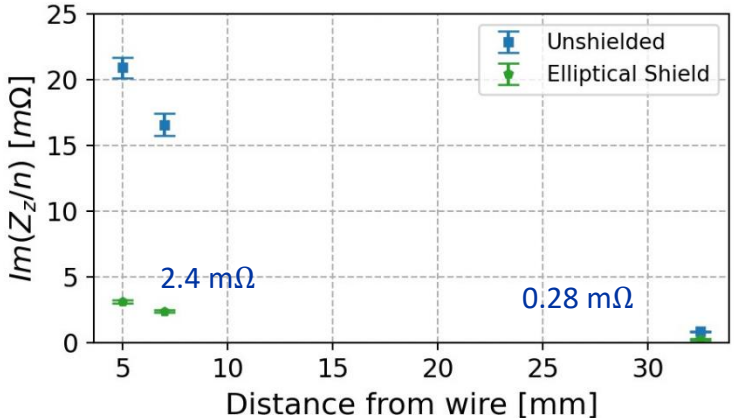

Option C: Box Shield

- Box on top of wire and Aluminum Nitride support

# Option B: Elliptical Shield

Elliptical pipe shielding the wire from the beam

Total budget of Longitudinal Effective Impedance:

- In Operation ~ 2.7 %
- Fully out ~ 0.3 %

Dissipated power below 10 W

# Option B: Elliptical Shield

Elliptical pipe shielding the wire from the beam

- Impedance contribution of the modules is not limiting.
- The impedance contribution of tapers has to be carefully evaluated and minimized.
- This design **might pose limitations** to the **forward physics in CMS (PPS2)**.

Total budget of **Longitudinal Effective Impedance**:

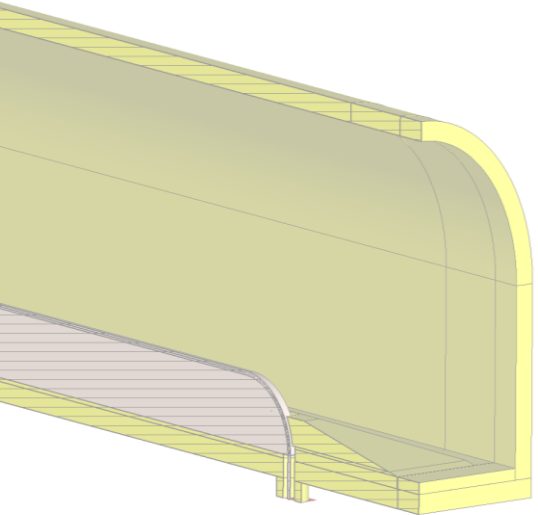

- In **Operation** ~ **2.7 %**
- **Fully out** ~ **0.3 %**

Dissipated power below **10 W** (below **0.5 %**)

# Impedance optimization options

External

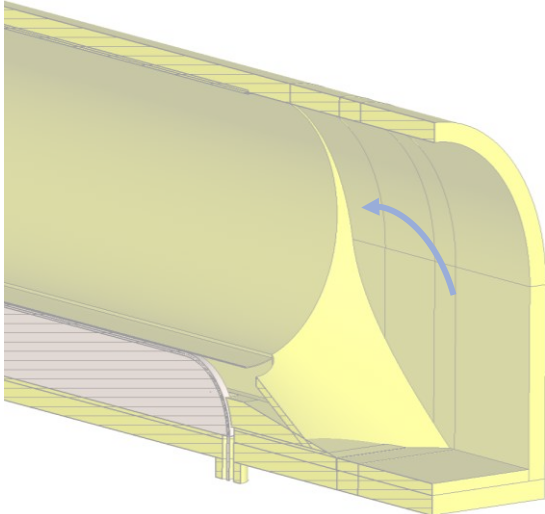

**Option A: RF load**

- No modification to the module
- External circuit at wires' termination

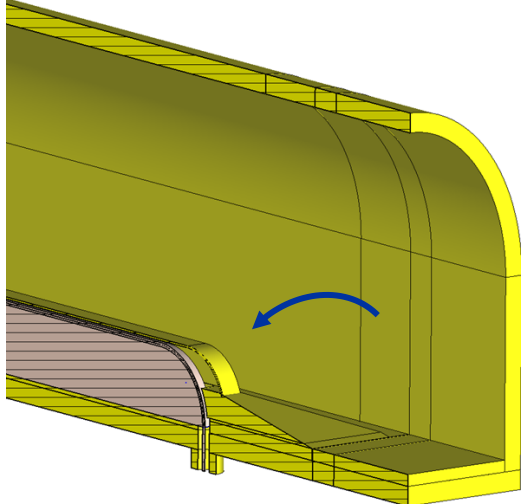

Internal shield

**Option B: Elliptical Shield**

- Elliptical pipe as shield
  - Thin window
  - Tapering

**Option C: Box Shield**

- Box on top of wire and Aluminum Nitride support

# Option C: Box Shield

**Box shield** fully covering the wire and the aluminum nitride support

- In terms of:
- Total budget of **Longitudinal Effective Impedance**
  - Dissipated **power**
- Equal to the elliptical shield option**

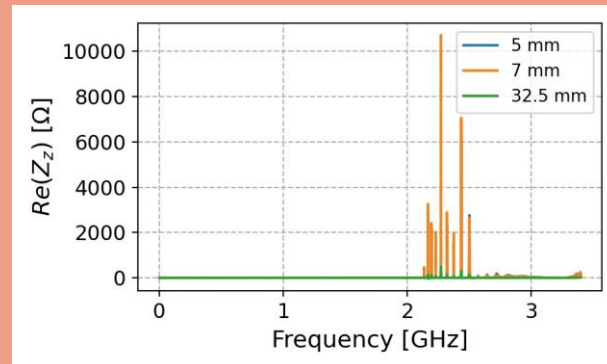

# Option C: Box Shield

**Box shield** fully covering the wire and the aluminum nitride support

- **Resonances** above 2 GHz not present in the elliptical shield option

In terms of:

- Total budget of **Longitudinal Effective Impedance**
  - Dissipated **power**

**Equal to the elliptical shield option**

# Outline

- 1. **Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
- 2. **Unshielded BBWC Impedance** ..... Slides 10-12
- 3. **Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
- 4. **Interconnections considerations** ..... Slide 25
- 5. **Conclusions** ..... Slide 27

# The interconnections

**Shielding** the wire → The **major impedance contribution** could come from the **transitions and interconnections**:

- **Bellows**

TCDQ collimator has:

1. **Cardan bellows**:

1. Allowing a **transverse displacement of  $\pm 20$  mm**
2. With **impedance shielding**

2. Transition from elliptical to round chambers

**This option must be discussed with vacuum team**

- **Tapers:**

Careful impedance design is needed to minimize impedance contribution.

# Outline

- 1. **Introduction** ..... Slides 4-8
  - 1.1. The Beam-Beam Wire Compensator
  - 1.2. Impedance Studies
  
- 2. **Unshielded BBWC Impedance** ..... Slides 10-12
  
- 3. **Mitigation options** ..... Slides 14-23
  - 3.1. RF load termination
  - 3.2. Elliptical shield
  - 3.3. Box shield
  
- 4. **Interconnections considerations** ..... Slide 25
  
- 5. **Conclusions** ..... Slide 27

# Conclusions

## Unshielded BBWC

Behaviour in terms of impedance and power loss:

- Significant impedance contribution
- Need for a mitigation

## Mitigation options

Three mitigation options presented:

- External: terminating the wire with a RF Load

- Not a solution in terms of impedance
- Should be considered for protection of power converters

- Internal shields:

- Elliptical shield:
  - Best solution in terms of effective longitudinal impedance at low frequency and power loss
- Box shield:
  - Feasible solution but several resonances above 2 GHz

## Bellows and Tapers

Impedance main source after shielding

- Possibility of shielded bellows (TCDQ)
- Need for careful design of tapers

Thank you for the attention 😊

BBWC
