 - SM Results
 - Anomalous coupling effects

5 Summary

- Higgs sector in SM is not well explored, in particular *HHH*, *HHHH* and *VVHH* couplings are still not well measured.
- Few processes can probe these coupling.
 - VBF mechanism for HH production

The obtained bound are $-5.4 < \kappa_{HHH} < 11.4$ and $-0.1 < \kappa_{V_2H_2} < 2.1$ at 95% confidence level ¹. The bound comes from both the couplings WWHH and ZZHH.

 oo
 oo

Motivation : $H \rightarrow Z^*Z^* \rightarrow 4l$

• • Higgs-strahlung : HHV (V=W, Z) production

At the HL-LHC the bound will be quite weak $-9<\kappa_{V_2H_2}<11$ $^2.$

• VVH (V=W, Z) production

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

We can probe two VVHH couplings separately.

²Eur. Phys. J. Plus (2019) 134: 288

Motivation : $H \to Z^*Z^* \to 4l$

- One loop EW correction to Higgs partial decay widths.
- These processes are sensitive to *HHH* and *VVHH* couplings beyond LO.
- Effect of anomalous *HHH* and *ZZHH* coupling on the Higgs decay width.
- Effect of scaling of *ZZWW* coupling on Higgs decay width.

Techniques to compute amplitudes :

- We compute helicity amplitudes by using spinor helicity formalism at the matrix element level.
- We use FeynArts to generate diagrams and then we use FormCalc to generate raw Feynman amplitudes.
- The helicity amplitudes have been computed using our generic FORM routines.
- The final amplitudes are written in terms of spinor product and dot products among the vector currents, momenta and polarizations.

Amplitude computation				

- We adopt t'Hooft-Veltman (HV) dimensional scheme to compute the amplitudes.
- In this scheme, the loop part has been computed in *d*-dimension and the rest has been computed in 4-dimension.

$$\bar{\gamma^{\mu}}\bar{\gamma_{\mu}} = d \qquad \vec{q} = q + \vec{q}$$

- We use the package 'OneLOop' for scalar integrals computation.
- We use an in-house routine *OVReduce*, based on Oldenborgh-Vermaseren reduction techniques to reduce tensor integrals in terms of scalar integrals.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○ ● ●

- The trace is inconsistent, as one can get different results depending on the different starting points of the trace.
- The formal treatment of $\gamma^5 = \frac{i}{4!} \epsilon_{\mu\nu\rho\sigma} \gamma^{\mu} \gamma^{\nu} \gamma^{\rho} \gamma^{\sigma}$ is not consistent in *d*-dimension as the anti-symmetric tensor $\epsilon_{\mu\nu\rho\sigma}$ lives in 4-dimension.
- We use KKS scheme (Korner-Kreimer-Schilcher) in which all γ^5 -matrices has to be taken to a particular vertex ('reading point') by anti-commuting with other γ -matrices. Then one can do d-dimensional algebra and compute trace.

 Soc

 Renormalization, CMS and Input parameter scheme
 OL
 EW
 Renormalization

We use on-shell renormalization scheme to calculate the required CTs for this process. The SM parameters are renormalized as

$$e_0 = (1 + \delta Z_e)e, \quad M^2_{W,0} = M^2_W + \delta M^2_W, \quad \text{and} \quad M^2_{Z,0} = M^2_Z + \delta M^2_Z.$$

We also need wave function(w.f.) renormalization of involve fields in this process to remove the UV divergences. The required w.f. renormalization are defined as

$$Z_{0} = (1 + \frac{1}{2}\delta Z_{ZZ})Z + \frac{1}{2}\delta Z_{ZA}A, \quad A_{0} = (1 + \frac{1}{2}\delta Z_{AA})A + \frac{1}{2}\delta Z_{AZ}Z,$$
$$W_{0}^{\pm} = (1 + \frac{1}{2}\delta Z_{W})W^{\pm}, \quad H_{0} = (1 + \frac{1}{2}\delta Z_{H})H, \quad f_{i,0}^{L} = (\delta_{ij} + \frac{1}{2}\delta Z_{ij}^{f,L})f_{j}^{L}.$$

CMS and OL Renormalization

 The complex mass scheme (CMS) has been used to treat unstable particle in one loop electroweak correction. The unstable masses are defined with a complex part as

$$m_V^2 \to \mu_V^2 = m_V^2 - im_V \Gamma_V,$$

where V = W, Z and Γ_V is the corresponding decay width. This treatment also makes Weinberg angle complex as $\cos^2 \theta_W = \mu_W^2/\mu_Z^2$.

- The renormalization in CMS has been done in a modified version of the on-shell scheme where the renormalized mass is the pole of the corresponding propagator in the complex plane. When renormalized conditions being imposed, one need to perform the self energy computation with complex momenta.
- This computation can be done with Taylor expansion of self energies about the real mass and maintaining the one loop accuracy.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ・三 ・ のへぐ

Input parameter scheme

- $\bullet\,$ Different choice of α leads to different input parameter scheme.
- We calculate this process in $\alpha(M_Z)$ and G_F input parameter scheme.
- In $\alpha(M_Z)$ scheme, $\alpha(0)$ is evolved via renormalization-group equations from zero-momentum transfer to Z pole.
- In G_F scheme, the effective value of α is derived from the Fermi constant G_F in muon decay process.
- The charge renormalization constant contains mass singular terms like $\alpha \log m_f$ from each light fermion f which remain uncancelled in the EW corrections.
- Running of α absorbs these mass singular terms from the charge renormalization.

000	00	00000000000000		•0000000
Summa	irv			

- We have studied one loop EW correction to $H \to \nu_e \bar{\nu}_e \nu_\mu \bar{\nu}_\mu$ and $H \to e^+ e^- \mu^+ \mu^-$ processes.
- These processes have significant dependency on *HHH* coupling.
- The relative increment goes from $\sim 0.5\%$ to $\sim -27\%$ depending upon the allowed scaling of HHH coupling.
- The dependencies of ZZHH coupling on partial decay width is marginal in $\alpha(M_Z)$ scheme but in G_F scheme, the RI goes from -7% to 5% depending on κ_{ZZHH} .
- The partial decay width also depends on ZZWW coupling strongly.
- Gauge invariance is maintained with the scaling of *HHH* in this process, whereas the same is not maintained with the scaling of *ZZHH* and *ZZWW* couplings.
- A better theory is needed to vary *VVHH* and *VVVV* couplings with out disturbing the gauge invariance.

OL EW Renormalization

The counterterms can be calculated by imposing suitable renormalization conditions. The required counterterms read as

$$\begin{split} \delta M_W^2 &= \operatorname{Re} \Sigma_T^W(M_W^2), \quad \delta Z_W = -\operatorname{Re} \frac{\partial}{\partial k^2} \Sigma_T^W(k^2) \bigg|_{k^2 = M_W^2}, \\ \delta M_Z^2 &= \operatorname{Re} \Sigma_T^{ZZ}(M_Z^2), \quad \delta Z_{ZZ} = -\operatorname{Re} \frac{\partial}{\partial k^2} \Sigma_T^{ZZ}(k^2) \bigg|_{k^2 = M_Z^2}, \\ \delta Z_{ZA} &= 2 \frac{\Sigma_T^{AZ}(0)}{M_Z^2}, \quad \delta Z_{AA} = -\frac{\partial}{\partial k^2} \Sigma_T^{AA}(k^2) \bigg|_{k^2 = 0}, \\ \delta Z_e &= -\frac{1}{2} \delta Z_{AA} - \frac{s_W}{c_w} \frac{1}{2} \delta Z_{ZA}, \quad \delta Z_H = -\operatorname{Re} \frac{\partial}{\partial k^2} \Sigma^H(k^2) \bigg|_{k^2 = M_H^2}, \\ \delta Z_{ii}^{f,L} &= -\operatorname{Re} \Sigma_{ii}^{f,L}(m_{f,i}^2) - m_{f,i}^2 \frac{\partial}{\partial k^2} \operatorname{Re} [\Sigma_{ii}^{f,L}(k^2) + \Sigma_{ii}^{f,R}(k^2) + \Sigma_{ii}^{f,L}(k^2)] \end{split}$$

The self energies Σ , can be calculated from self energy of *W*-boson, *Z*-boson, photon(also $Z\gamma$) and *H*-boson propagators.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○ ● ●

CMS and OL Renormalization

 The complex mass scheme(CMS) has been used to treat unstable particle in one loop electroweak correction. The unstable masses are defined with a complex part as

$$m_V^2 \to \mu_V^2 = m_V^2 - im_V \Gamma_V,$$

where V = W, Z and Γ_V is the corresponding decay width. This treatment also makes Weinberg angle complex as $\cos^2 \theta_W = \mu_W^2 / \mu_Z^2$.

- The renormalization in CMS has been done in a modified version of the on-shell scheme where the renormalized mass is the pole of the corresponding propagator in the complex plane. When renormalized conditions being imposed, one need to perform the self energy computation with complex momenta.
- This computation can be done with Taylor expansion of self energies about the real mass and maintaining the one loop accuracy.

The renormalized counterterms in CMS are

$$\begin{split} \delta\mu_W^2 &= \Sigma_T^W(M_W^2) + (\mu_W^2 - M_W^2)\Sigma_T'^W(M_W^2) + c_T^W + \mathcal{O}(\alpha^3), \\ \delta\mu_Z^2 &= \Sigma_T^{ZZ}(M_Z^2) + (\mu_Z^2 - M_Z^2)\Sigma_T'^Z(M_Z^2) + \mathcal{O}(\alpha^3), \\ \delta\mathcal{Z}_W &= -\Sigma_T'^W(M_W^2), \quad \delta\mathcal{Z}_{ZZ} = -\Sigma_T'^{ZZ}(M_Z^2), \\ \delta\mathcal{Z}_H &= -\Sigma'^H(M_H^2), \quad \delta\mathcal{Z}_{ZA} = \frac{2}{\mu_Z^2}\Sigma_T^{AZ}(0), \quad \delta\mathcal{Z}_{AA} = -\Sigma_T'^{AA}(0). \end{split}$$

 Summary

 00
 00
 00000000000
 00000
 00000000
 00000000

The charge renormalization constant δZ_e is calculated from the photon self energy renormalization constant δZ_{AA} as it can be seen from Equ. 31. The renormalization constant δZ_{AA} contains mass singular terms $\alpha \log m_f$ where m_f is the mass of the fermion. These contribution comes from every light fermion loop in δZ_{AA} and remain uncancelled in EW corrections. To renormalize the electric charge, the standard QED on-shell renormalization condition is being imposed in the Thomson limit , where the photon momentum transfer is zero. This renormalize the QED coupling $\alpha = \alpha(0)$ at $Q^2 = 0$. To have the weak coupling α at desire scale $(Q^2 \sim M_Z^2)$ one need running of α from $Q^2 = 0$ to $Q^2 = M_Z^2$. The running of α remove the mass singular terms from the charge renormalization.

The choice of the running of the coupling α leads to the notion of the input parameter scheme. In $\alpha(M_Z)$ input parameter scheme, the $\Delta\alpha(M_Z)$ is given by

$$\Delta\alpha(M_Z) = \frac{\alpha(0)}{3\pi} \sum_{f \neq t} N_f^c Q_f^2 \left[\ln\left(\frac{M_Z^2}{m_f^2}\right) - \frac{5}{3} \right].$$
(1)

The shift in charge renormalization $\delta Z_e|_{\alpha(M_Z^2)} \rightarrow \delta Z_e|_{\alpha(0)} - \frac{1}{2}\Delta\alpha(M_Z^2)$, will remove all mass singularities in δZ_e . The numerical value of $\alpha(M_Z)$ has been extracted from an experimental analysis of e^+e^- annihilation to hadrons.

Motivation	Diagrams	Calculation	SM Results and Anomalous coupling effect	Summary
000	00	0000000000000		0000000

In α_{G_F} scheme, the electromagnetic coupling is derived from the Fermi constant as

$$\alpha_{G_F} = \frac{\sqrt{2}G_F M_W^2 (M_Z^2 - M_W^2)}{\pi M_Z^2} = \alpha(0)(1 + \Delta r) + \mathcal{O}(\alpha^3)$$
(2)

$$\Delta r = \Delta \alpha(M_Z) - \Delta \rho \frac{c_W^2}{s_W^2} + \Delta r_{rem}.$$
(3)

In this scheme, the shift in charge renormalization is given by $\delta Z_e|_{G_F} \rightarrow \delta Z_e|_{\alpha(0)} - \frac{1}{2}\Delta r$, where the Δr is the radiative corrections to muon decay. The Δr is given by

$$\Delta r = \Sigma_T^{AA}(0) - \frac{c_W^2}{s_W^2} \left(\frac{\Sigma_T^{ZZ}(M_Z^2)}{M_Z^2} - \Sigma_T^W(M_W^2) M_W^2 \right) + \frac{\Sigma_T^W(0) - \Sigma_T^W(M_W^2)}{M_W^2} + 2\frac{c_W}{s_W} \frac{\Sigma_T^{AZ}(0)}{M_Z^2} + \frac{\alpha}{4\pi s_W^2} \left(6 + \frac{7 - 4s_W^2}{2s_W^2} \log c_W^2 \right).$$
