Introduction

- ⤴ **ALiBaVa**[1] is a portable read-out system developed for test sensors in (s)LHC-like experiments. It provides a real-time GUI and data format for custom (ROOT) analysis.
- ⤴ There is the interest on the SNR and the efficiency of detectors. In particular it is interesting to know the performances of **slim edges** (cut) detectors, compared to the uncut ones.
- ⤴ It is interesting to study the relation between the occupancy and the efficiency of a detector by a **threshold scan**:
 - ⤴ To vary the threshold mean to scale the occupancy by a factor proportional to the integral of the distribution[2].
- ⤴ Our objectives are to study the signal distributions and to characterize slim edge sensors:
 - comparing cut and uncut detectors;
 - comparing inner strips with edge-strips (outer strips).

Materials

⤴ Sensors:

- ⤴ (CMS, p-on-n, unirradiated, 128 strips.)
- ⤴ GLAST cut (Si oxide passivated, laser-scribed and cleaved), p-on-n, unirradiated, 8 strips. (Thanks to Bernard Philips and Marc Christophersen!)
- ⤴ GLAST uncut, p-on-n, unirradiated, 8 strips.

Experimental set-up

✧ **Set-up:**

- $^{90}\text{Sr}/^{90}\text{Y}$ (disintegration energies 0.5/2.3 MeV, half-life 29y/64h).
- Scintillator + photomultiplier (PM) tube from UCSC.
- ALiBaVa system from INFN Florence.

✧ **Settlings:**

- $V_{\text{bias}}=[1,10,20,50,100,150,200,500]$ V.
- Beetle settlings: high gain, "Kazu" configuration.
- Noise measurements: detector not in front of the source.

Analysis

- ⤴ *Noise measurement analysis:*
 - ⤴ Fit of the distribution to get the **sigma**.
 - ⤴ Occupancy threshold scan and fits to cross-check.
 - ⤴ *Signal measurements analysis:*
 - ⤴ Time cut.
 - ⤴ Clustering: amplitude cut for seed and neighbours.
 - ⤴ Fit of the distribution to get the **MPV** and a sigma of noise.
- => **SNR=MPV/sigma** (from noise distribution fit).
- ⤴ *Analysis vs. bias voltage.*
 - ⤴ *Analysis vs. channel index: look at the edges!*

Experimental results

GLAST cut (inner channels):

Noise: distribution

Distribution of amplitudes of all channels

Vbias=200V

σ=4.46 ADCs

D·E

Dipartimento di Energetica

"Sergio Stecco"

Experimental results

- GLAST cut (inner channels):
- Noise: occupancy threshold scan.

Graph

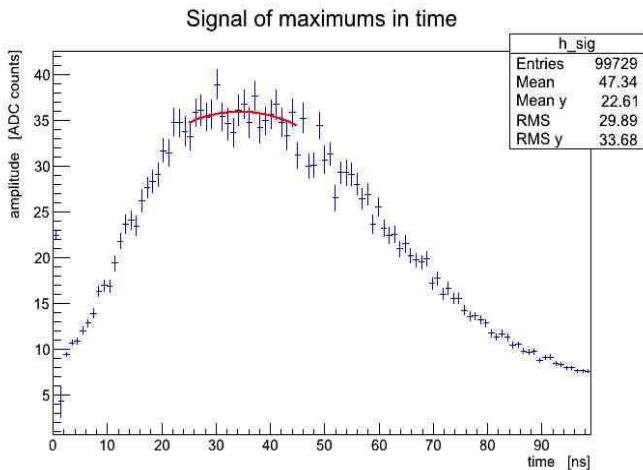

▲ **Sigma=6.34 ADCs**

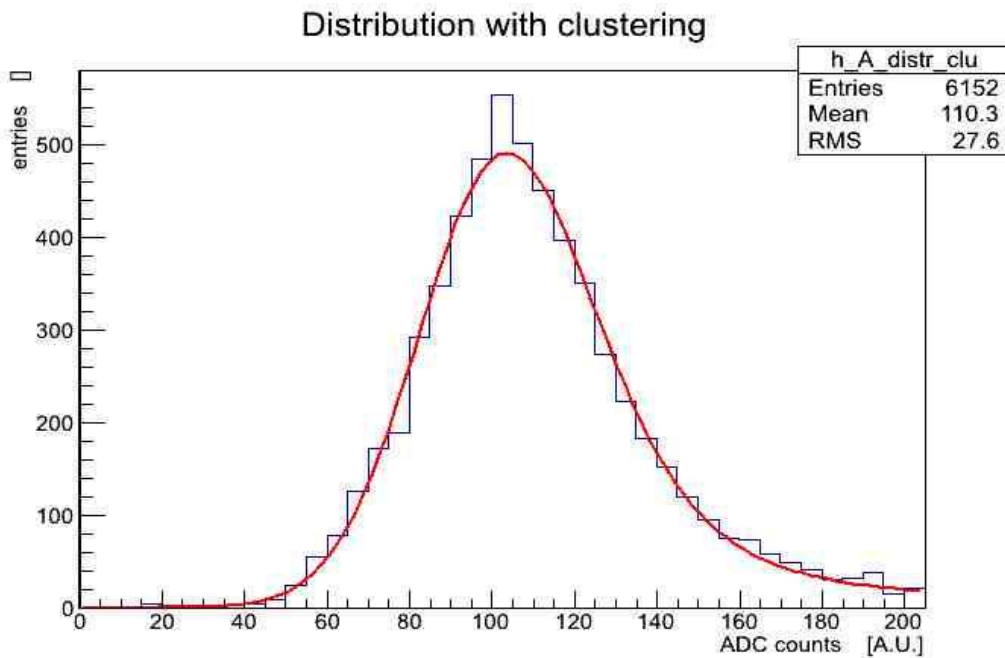

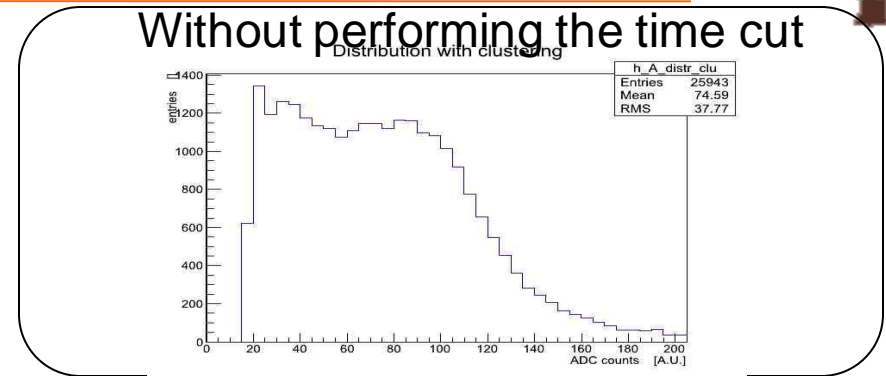

Experimental results

GLAST cut (inner channels):
Signal: in time and distributions

- Time cut: [25,45]ns
- Correction factor: 1.013.

Vbias=200V

- MPV=103.62*1.013 ADCs (from the CMS, expected 107.33!).
- Sigma(Gaussian)=18.62 ADCs.

$$\text{SNR} = 103.26 * 1.013 / 4.46 = 23.64$$

Experimental results

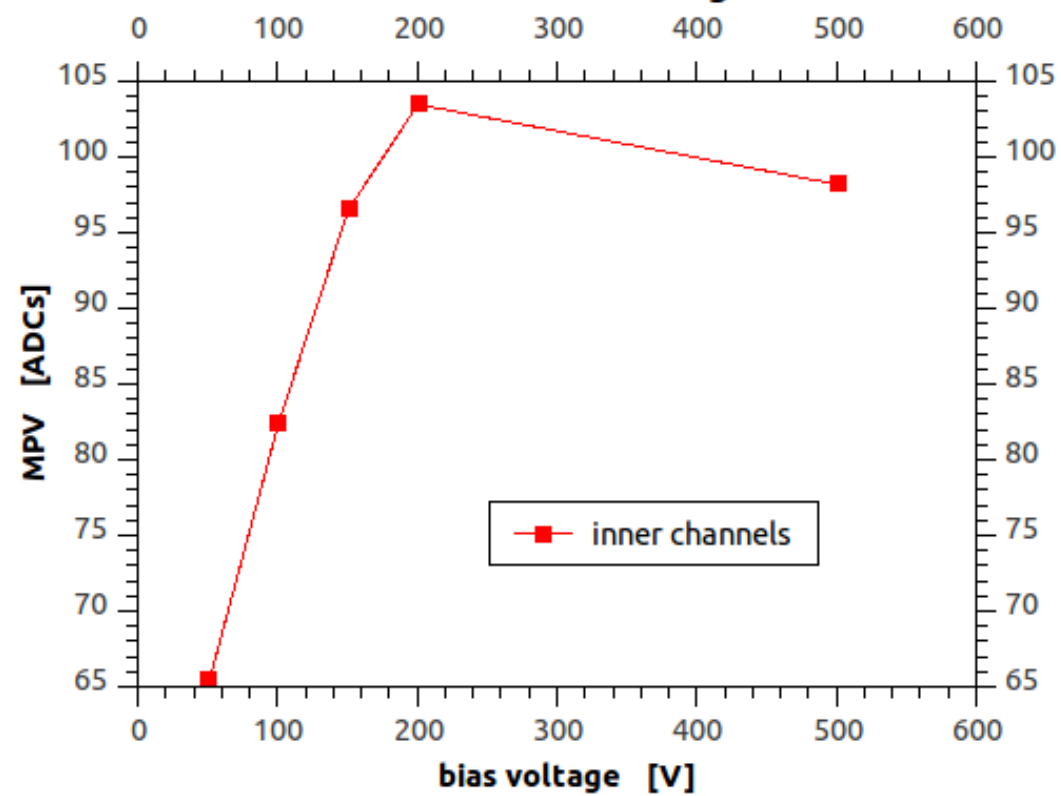

GLAST cut (inner channels):
Results versus bias voltage

sigma versus bias voltage

MPV versus bias voltage

Experimental results

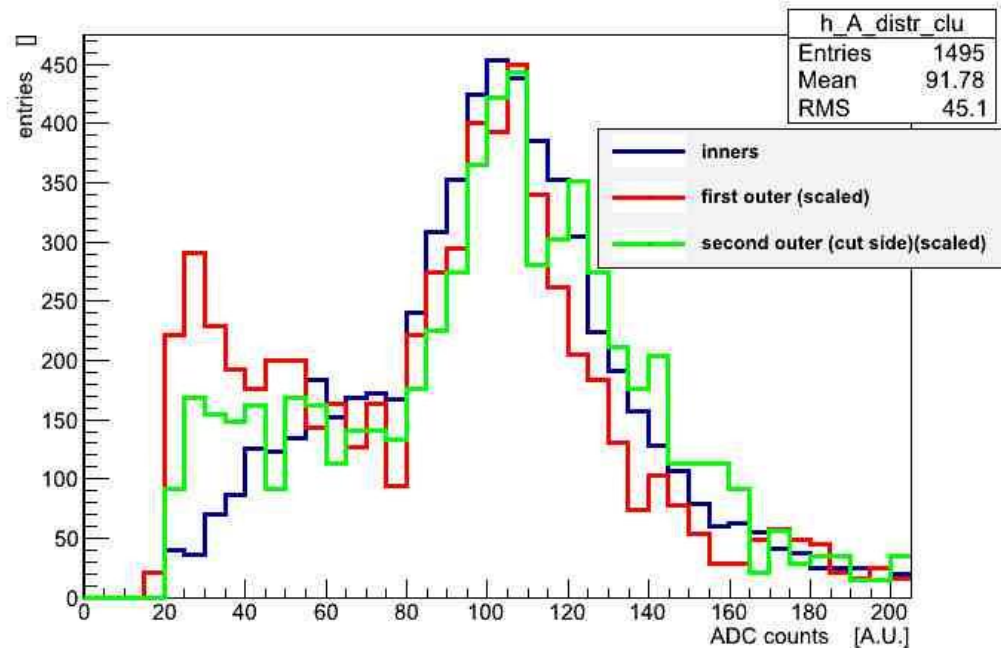

Comparison inner-outer channels: the anomaly of the outer channels

Noise distributions

Distribution of amplitudes of all channels

Signal distributions

Outer noise larger because of the interstrip capacitance.

Outer signals have a tail!?!

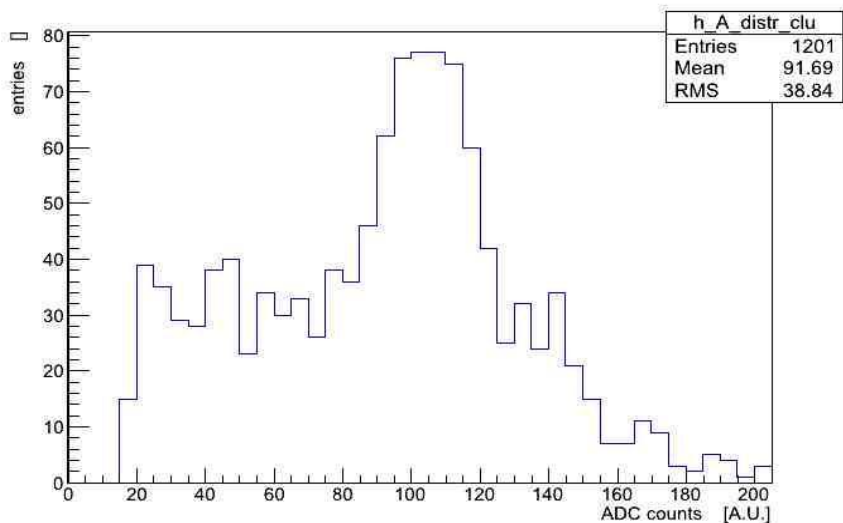

Experimental results

Comparison inner-outer channels: the anomaly of the outer channels

An inner channel without adding the neighbours...

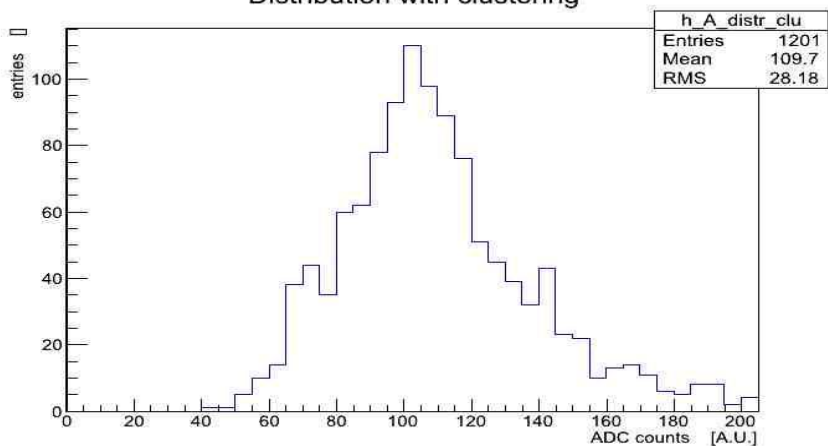

The highest neighbours distribution: the tail!!!

Adding the neighbours...

Distribution with clustering

The outer channels has the guard ring as neighbors, which is not read out.

Experimental results

Comparison inner-outer channels: reconstructing the outer channels

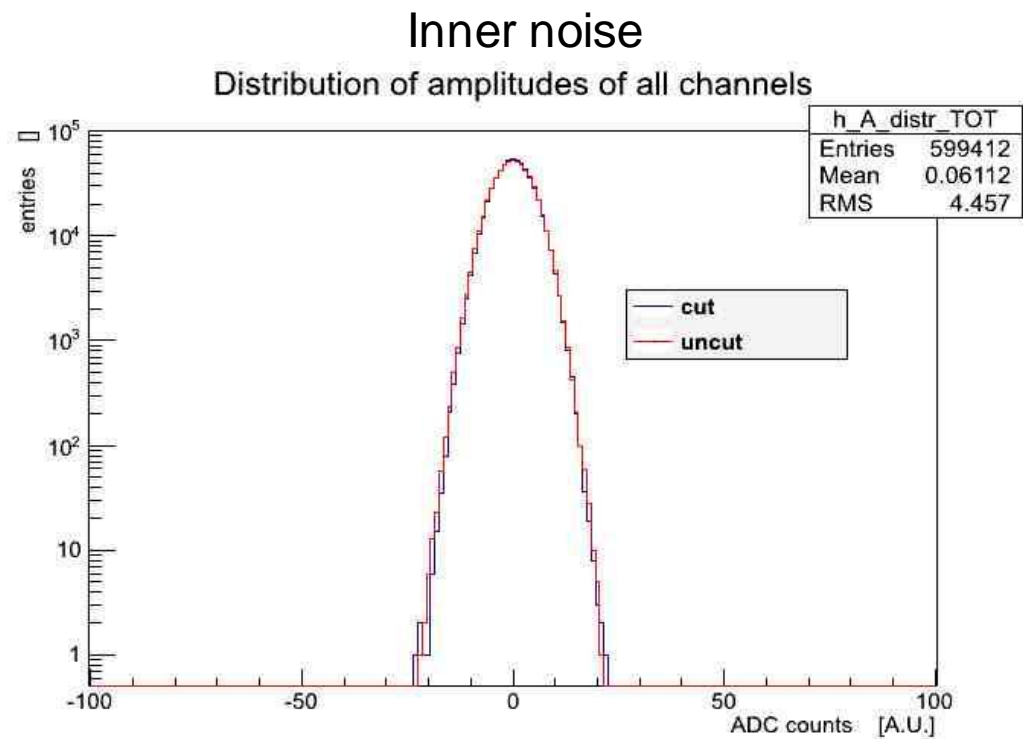

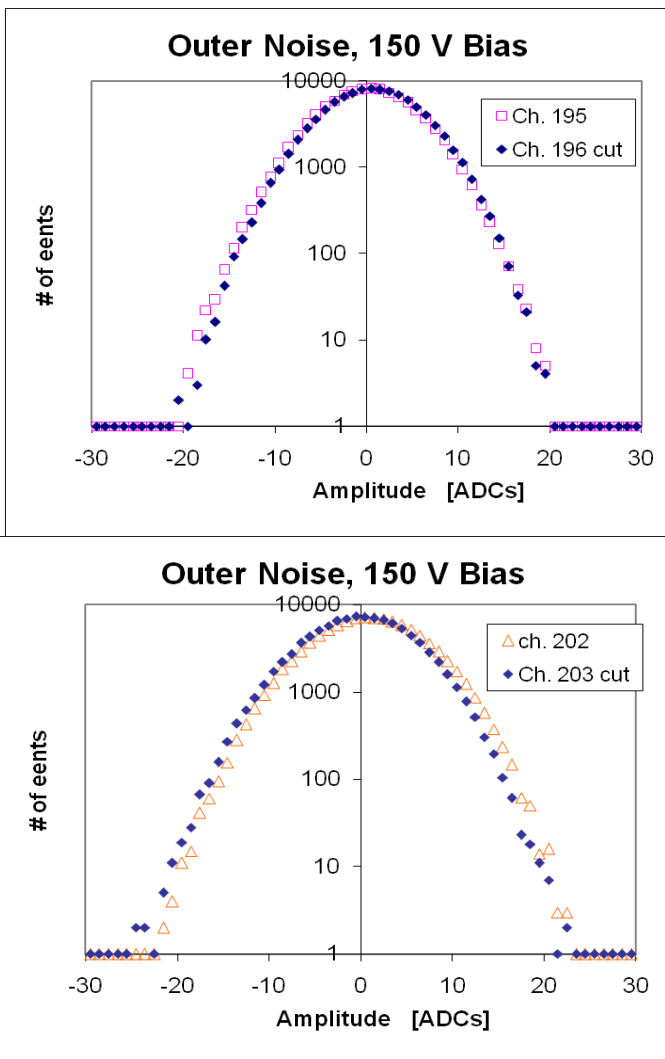

Experimental results

Comparison cut-uncut:

Noise:

Vbias=150V

About the same sigma!

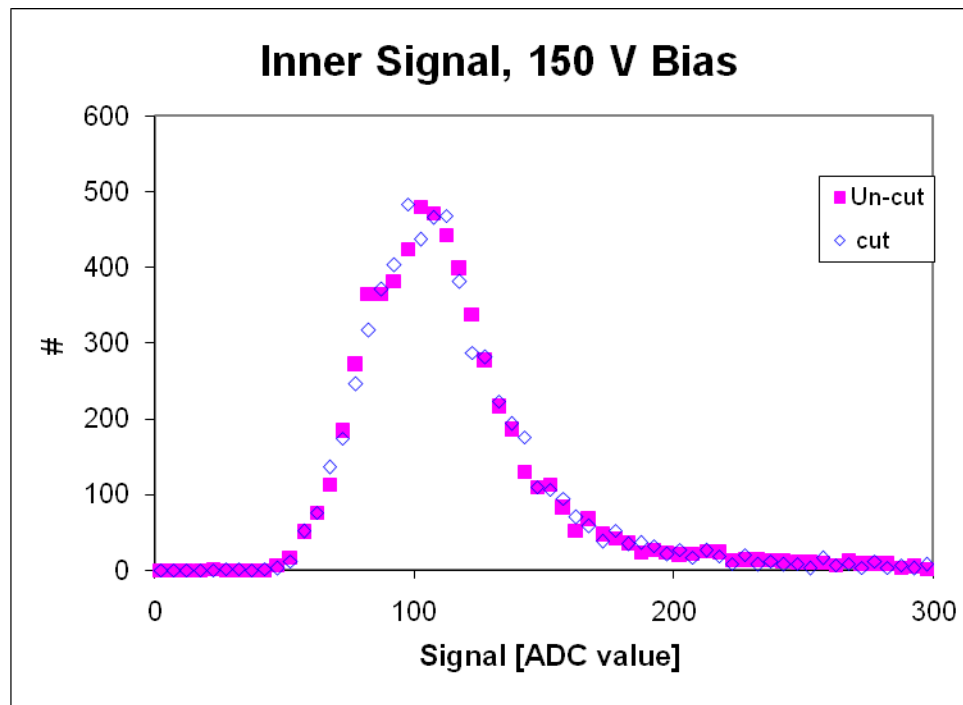

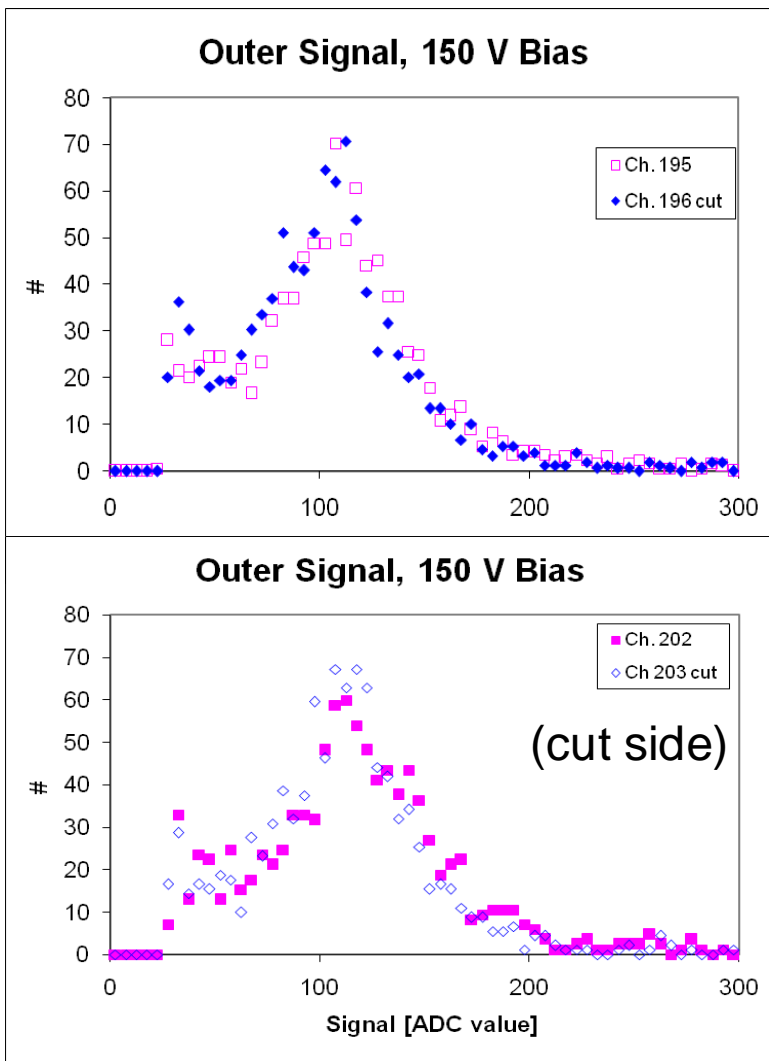

Experimental results

Comparison cut-uncut:

Signal:

About the same pulse height!

Discussion

Limits:

- ⤴ No calibration.
- ⤴ No separated pedestal run.

On the results:

- ⤴ Width of the distribution:
 - ⤴ Noise.
 - ⤴ Dispersion of the path length.
 - ⤴ Natural broadening of the Landau described by Meroli[4].
- ⤴ MPV decrease from 200V to 500V.
- ⤴ The border strips clearly have a tail due to the charge sharing with the bias ring, in general due to the contribution as a neighbours of channels unread-out.

Conclusions

Work done:

- ✧ Tested ALiBaVa.
- ✧ Tested detectors: SNR, efficiency.
- ✧ Compared cut-uncut.

Results:

- ✧ The cut sensor is as good as the uncut one: about the same sigma and the same pulse height.

Future works:

- ✧ Calibration.
- ✧ Test of other sensors (GLAST wonder baby, p-type).

Acknowledgements

- ✧ In particular, to Nicola Pacifico.

Spares

Dispersion of the path length:

$L_{\min} = 400 \mu\text{m}$

$L_{\text{MAX}} = 460.42 \mu\text{m}$

Assuming: $\text{MPV}(L_{\min}) = 100 \text{ ADCs}$

$\Rightarrow \text{MPV}(L_{\text{MAX}}) = 115.10 \text{ ADCs}$

\Rightarrow Dispersion of 15.1 ADCs

\Rightarrow ENOUGH TO EXPLAIN!

Spares

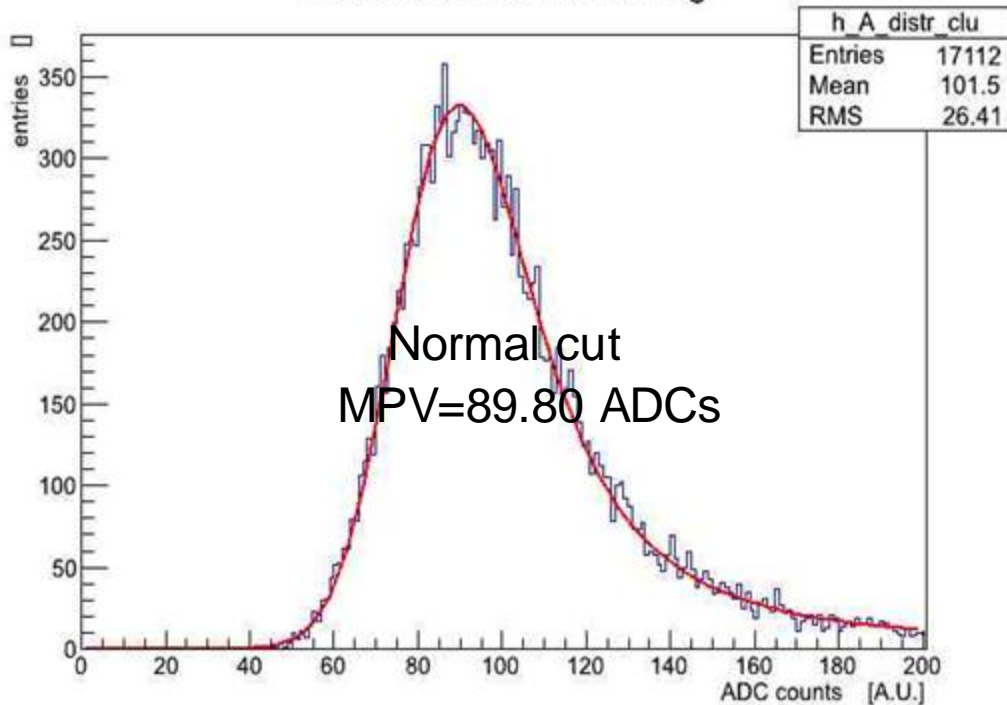

Warnings:

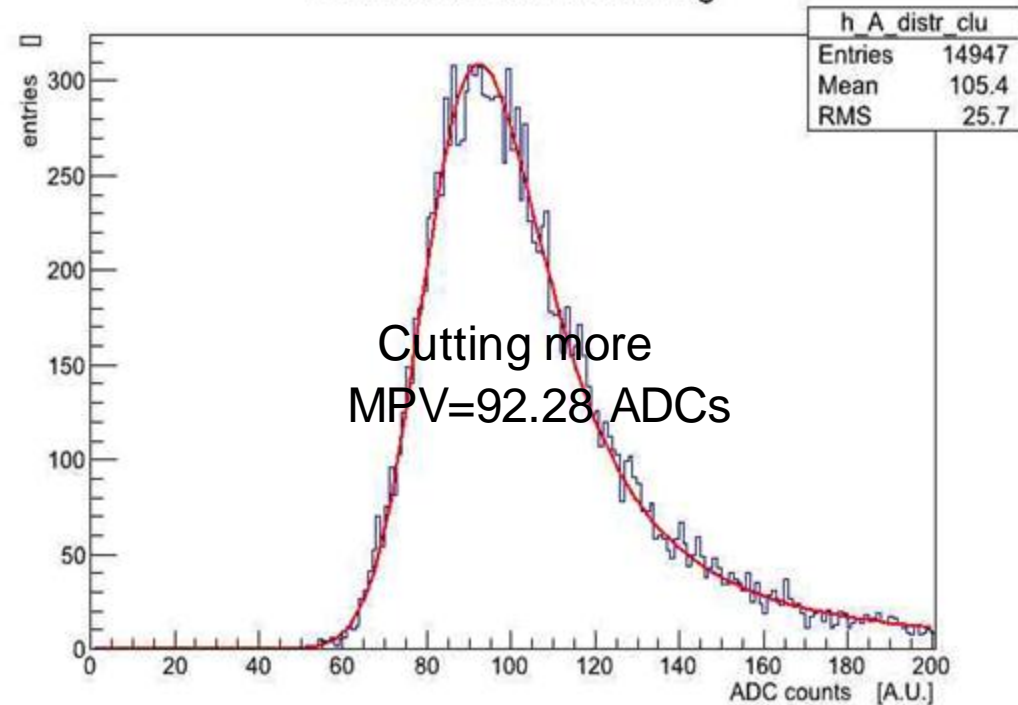

“Teppo's effect”[3]:

Be careful on the setting of the threshold: with a too high threshold, a Landau still appear and the MPV is biased (higher respect to the real).

Distribution with clustering

Distribution with clustering
