

Slow extraction w/ transverse noise

P. Arrutia, T. Levens

IPP MD days 2025

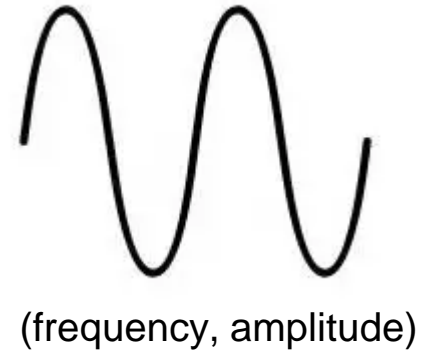

03/02/2025

Intro

- In PS, a small Transverse FeedBack (TFB) excitation is added to EAST during slow extraction to improve spill quality:
 - M. Delrieux: “intuitively it makes sense”
- Motivations of SPS dedicated MD:
 - Implement similar approach to SPS SFTPRO.
 - Better understand why/how this works.

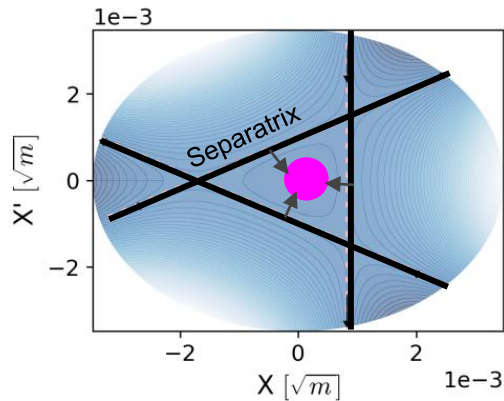

Concept: OP

- We use: nominal SFTPRO cycle w/ momentum ramp to push beam into resonance
- We add: horizontal sinusoidal excitation w/ TFB at freq. approx betatron tune, $\frac{1}{3} \cdot \text{frev}$) ~ “AC Dipole”, but on debunched beam.

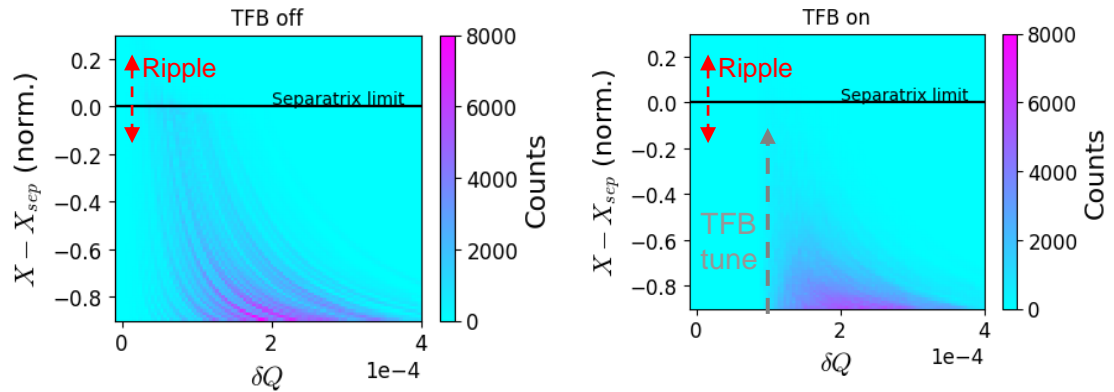

Concept: beam dynamics

The TFB kicks help particles cross into the resonance \rightarrow tune ripple has less impact on extraction rate.

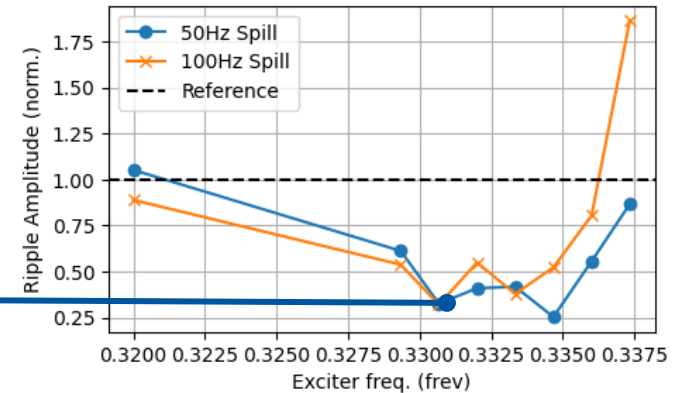

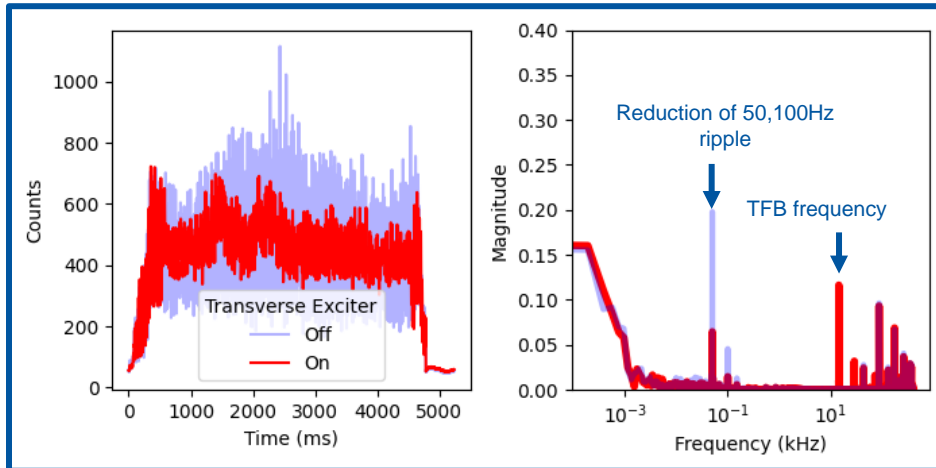

Beam tracking sim.

Results (i)

Clear spill quality improvement observed, in particular at low frequencies: 50Hz, 100Hz, ...

Setting (a): Spill quality improvement

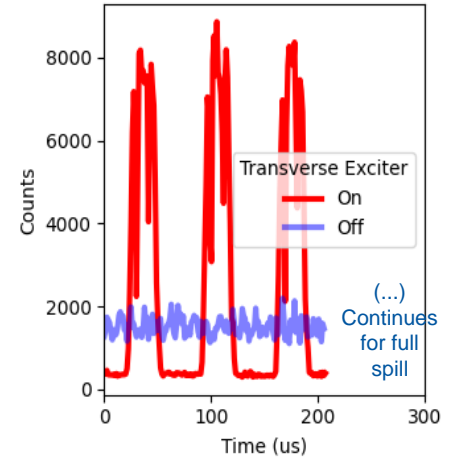

Results (ii)

- Technique can also be used to give bunched structure to the spill (starting from a debunched beam).
- Provides flexible way to create an “extinction region” for time of flight discrimination (could interest SHiP, alternative mode of operation).

Setting (b): bunched beams

TFB freq

$Q=1/3$

Wishes

- **SY-BI:** the new spill monitor (OTR-PMT) with 200MHz sampling acquisition. During 2024 MD, up to 800kHz, but not enough to probe 40MHz TFB limit.
- **SY-RF:** Controls Interface to program sinusoidal excitations on the TFB. During 2024 MD, excitation injected via BBQ channel using signal generator -> not viable long term.

Plans

- Push bandwidth limit of the TFB -> for spill quality, interesting to test higher harmonics of betatron tune.
- Study interplay between this manipulation and empty-bucket channelling -> potential to combine them or to replace EBC (possibly easier to set up and maintain)

Request: 1 dedicated MD slot
