

# Theoretical topics on Anomaly Detection

Marco Letizia

University of Genova and INFN Genova

## ***About me***

Theoretical physicist based at MaLGa@University of Genova & INFN Genova

- Statistical tests for model-agnostic searches
- Generative models in HEP and their validation

Frequent collaborators:

G. Grosso (MIT), M. Pierini (CERN), L. Rosasco (U. of Genova) R. Torre (INFN Genova), A. Wulzer (IFAE), M. Zanetti (U. of Padova).

## ***New physics beyond the Standard Model***

Dark matter; Strong CP problem; Matter/anti-matter asymmetry; Neutrino masses;  
Hierarchy problem; Flavor puzzle; ...

Thousands of LHC searches mostly targeting **specific models**

→ no observation of physics beyond the SM

What if the correct BSM scenario has not been formulated?

# *New physics* beyond the Standard Model

Design **model-agnostic strategies** to maximize the LHC discovery potential

# *New physics* beyond the Standard Model

Design **model-agnostic strategies** to maximize the LHC discovery potential

# New physics beyond the Standard Model

Design **model-agnostic strategies** to maximize the LHC discovery potential

## Hard problem:

- NP is a tiny and/or hidden effect
- Affecting few (unknown) observables over  $\infty$  many
- High dimensional problem
- Hard to simulate

## Partial model independence:

- Simplified models
- Effective field theories
- Bump hunts

## ML-driven model independence:

- Interesting phase space regions
- ~~Phenomenological modeling~~

## Model-agnostic strategies

Anomaly detection

Goodness-of-fit

# Anomaly detection

Identify interesting feature space regions by cutting on an anomaly score

## Outlier detection

### *Autoencoders*

Farina, Nakai & DS 1808.08992

$$L = \frac{1}{N} \sum_i (x_i - x_i^{reco})^2$$

## Overdensities

$$R(x) = \frac{p_{data}(x)}{p_{bkg}(x)}$$

*Learned with binary classifiers  
or neural density estimators.*

# Anomaly detection

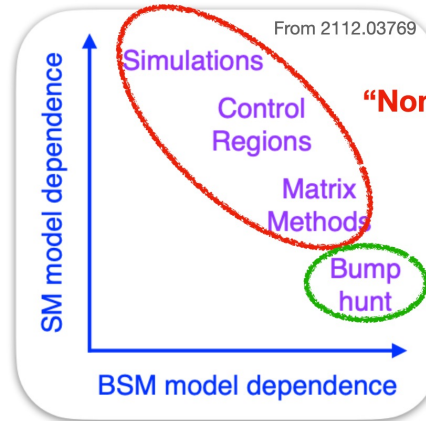

Identify interesting feature space regions by cutting on an anomaly score

## Outlier detection

### Autoencoders

Other ingredient is background estimation:

“Non-resonant AD”

“Resonant AD”

events with  $R(x) > 1.2$   
(density estimation method with Gaussian mixture models)

$$R(x) = \frac{p_{data}(x)}{p_{bkg}(x)}$$

$$L = \frac{1}{N} \sum_i (x_i - x_i^{reco})^2$$

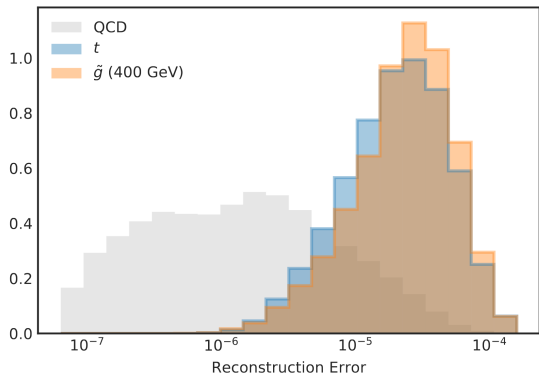

Learned with binary classifiers or neural density estimators.

Roberto Seidita's talk!

of neural density estimators.

## Goodness-of-fit

How well a reference model  $R$  (the SM) describes the measured data  $\mathcal{D}$ .

- Without referencing an alternative hypothesis
- Full statistical test: it outputs a global significance
- SM distribution is not known in closed form
  - Assume SM reference data are available  $\mathcal{R}$
- “Interpretable” to some extent

→ **two-sample hypothesis testing**

Assess if the null hypothesis  $H_0: p_R = p_{\text{true}}$  can be rejected from finite data.

## Two-sample testing

Test statistic  $t_{obs} = t(\mathcal{D}, \mathcal{R})$ ,  $t(\cdot, \cdot)$  must be a agnostic

Large  $t_{obs} \Rightarrow$  tension with  $H_0: p_R = p_{true}$ . How do we quantify?

$$p_{\text{value}} = \int_{t_{obs}}^{\infty} p(t|H_0) dt$$

$p(t|H_0)$  estimated:  
empirical distribution of possible  
outcomes under  $H_0$  with SM toy data

$$t_{H_0} = t(\mathcal{D}^{(R)}, \mathcal{R})$$

# Goodness-of-fit testing

Classical methods:

- Univariate (e.g. KS)
- Binned (e.g.  $\chi^2$ )

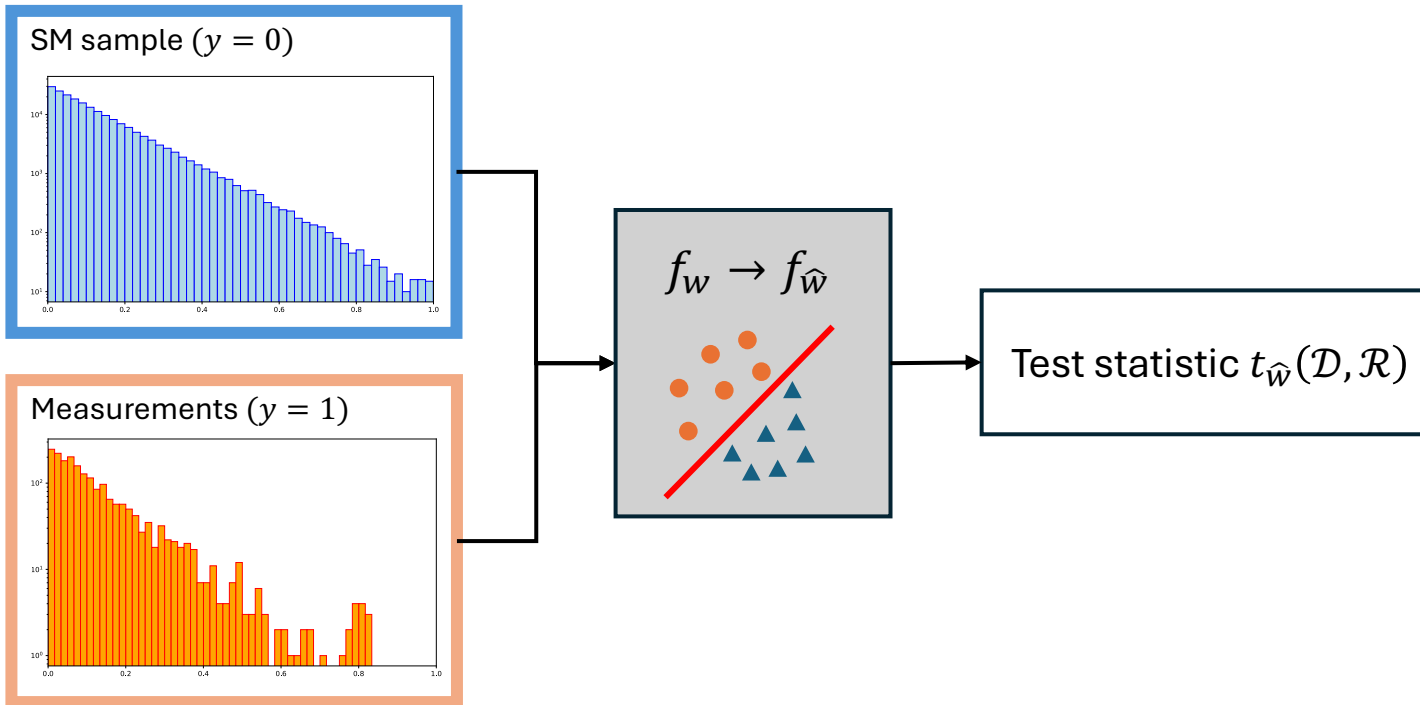

$$\chi^2 = \sum_{i=1}^{n_{\text{bins}}} \frac{(O_i - E_i)^2}{E_i}$$

Limited options for  $d > 3$  and large  $N$ :

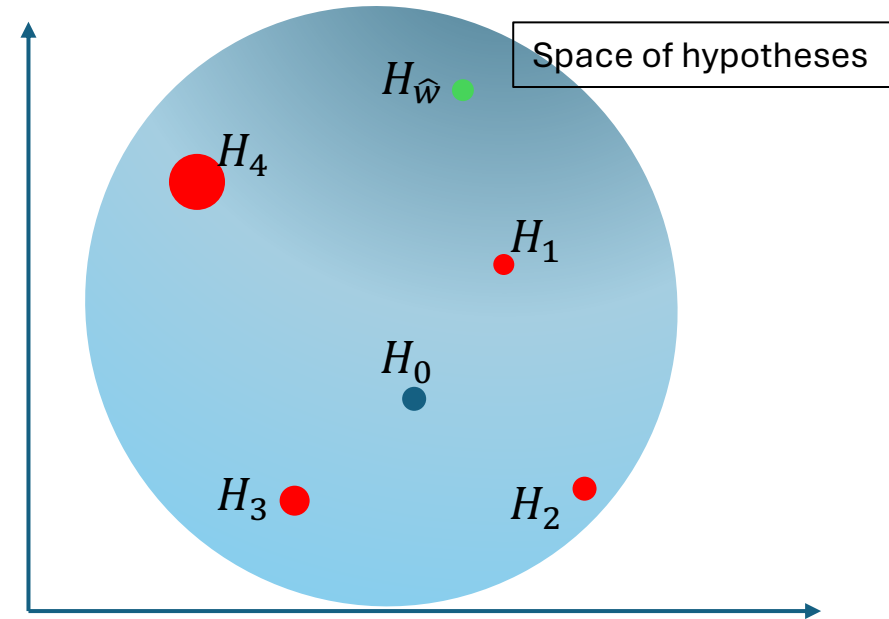

- *Maximum Mean Discrepancy*
- *Wasserstein Distance*
- *Classifier two-sample tests*
- *The New Physics Learning Machine*

# The New Physics Learning Machine

(unbinned!)

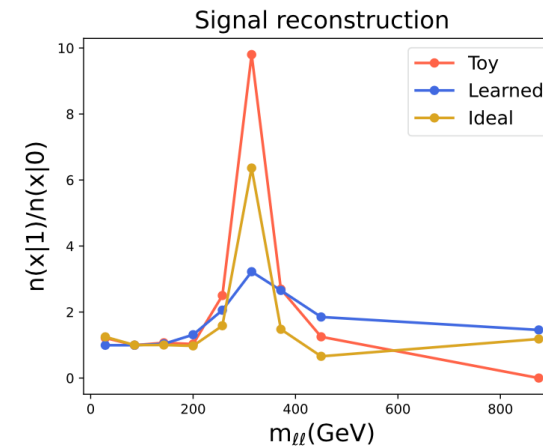

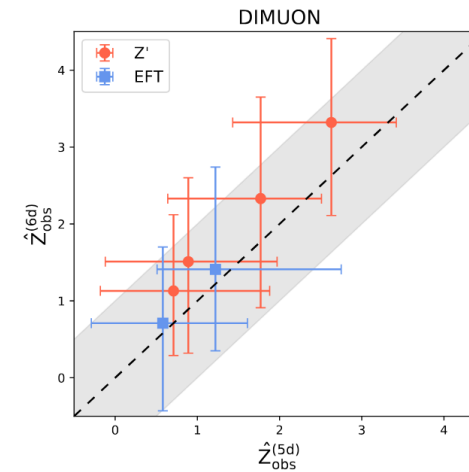

$$t_{\hat{w}}(\mathcal{D}, \mathcal{R}) = -2 \left[ \frac{N(SM)}{N_{SM}} \sum_{x \in \mathcal{R}} (e^{f_{\hat{w}}(x)} - 1) - \sum_{x \in \mathcal{D}} f_{\hat{w}}(x) \right] \approx 2 \log \frac{\mathcal{L}_{true}(\mathcal{D})}{\mathcal{L}_{SM}(\mathcal{D})}$$

$$f_{\hat{w}}(x) \approx \log \frac{n_{true}(x)}{n(x|SM)}$$

$$n(x) = N p(x)$$

# The New Physics Learning Machine

# Data Quality Monitoring

Grosso, Lai, ML, Pazzini, Rando, Rosasco, Wulzer, Zanetti, (2023), 2303.05413

Drift tube chambers from Legnaro INFN National Laboratory.

## DATASET:

- Drift times ( $t_i$ ): the four drift times of the muon track.
- Slope ( $\phi$ ): the angle with respect to the vertical axis.
- Reference data is collected in a controlled regime.
- Anomalies:
  - reduced voltage of cathodic strips to 75%, 50%, and 25% of their nominal value (-1.2 kV)
  - lowered front-end thresholds to 75%, 50%, and 25% of nominal value (100 mV)

Data: <https://zenodo.org/records/7128223>

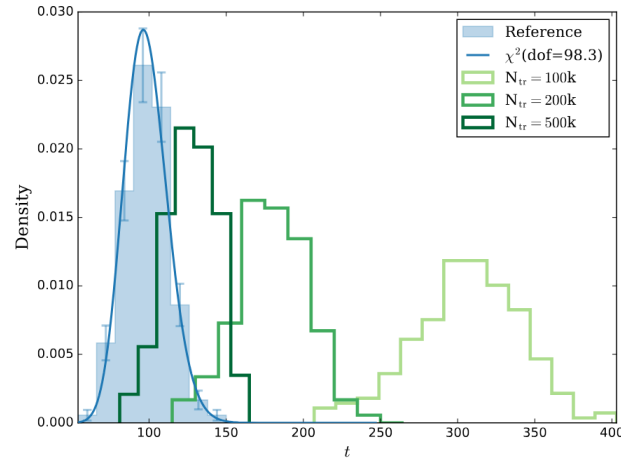

$$\bar{t}_{tr} \approx 0.5 \text{ sec}$$

# Evaluation of GenAI

Cappelli, Grosso, ML, Reyes-Gonzalez, Zanetti (out soon)

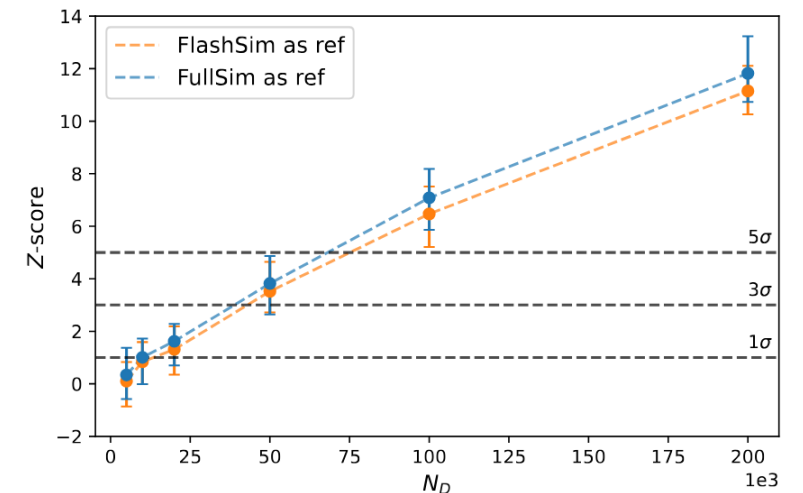

Compare data from a generative model against true data: relevant for fast simulations

- Synthetic data: normalizing flows trained on mixture of Gaussians

- Realistic case: FlashSim

[Francesco Vaselli et al. End-to-end simulation of particle physics events with Flow Matching and generator Oversampling. 2024. 2402.13684](#)

# Summary

- Two favors of model-agnostic searches:
  - Anomaly detection for the identification of interesting events/regions
  - Goodness-of-fit-based approaches: full agnostic statistical tests
- NPLM has yet to be applied to real analyses
  - Reliance on simulations → systematic uncertainties can be dealt with but tricky ([2111.13633](#))
  - Current pipeline is slow → fast implementation is available but currently without systematics ([2204.02317](#))
  - Scalability to high-dimensions: foundation models? Useful for low-level features ([Metzger, Xu, Sodini, Arrestad, Govorkova, Grosso, Harris \(2025\), 2502.15926](#))
  - There is no notion of a “best GoF test” (with highest power against any new physics signal): certain tests can be better at detecting specific signals.  
NPLM is found to be more robust than the alternatives (less biased).
- Can be used for other tasks: Data Validation, DQM, validation of GenAI

# Remarks

- How to evaluate signal-agnostic methods
  - Designed to detect the unexpected
  - Signal-benchmarks are reassuring (just for testing, no optimization) but not general
  - Comparison with ideal significance (fully aware: Neyman-Pearson) to estimate sensitivity loss
- Interpretability
  - How to characterize new physics if found?
  - Black box models do not help
- Re-interpretability
  - Reporting p-values is not enough
  - NPLM: trained model, background sample,  $p(t|H_0)$

*Thank you!*
