

# SUSY searches with $b$ -jets at CMS

Josh Thompson

Cornell University

26 October 2011

West Coast ATLAS forum, SLAC

# Outline

- Introduction
  - The LHC and CMS
  - SUSY and b-jets
- Analyses
  - CMS has two 2011 b-tagged SUSY searches
    - $MT2+b$ ,  $MET+b$
  - I will cover both but give more detail on  $MET+b$ 
    - Event selection
    - Background estimation methods
- Results and interpretation

# CMS at the LHC

J. Thompson, Cornell 26 Oct 2011

- proton–proton collider currently at 3.5 TeV per beam (designed for 7 TeV per beam)
- 9300 superconducting magnets (1232 dipoles) in a 27 km ring

CMS is 80m under Cessy, France

LHC

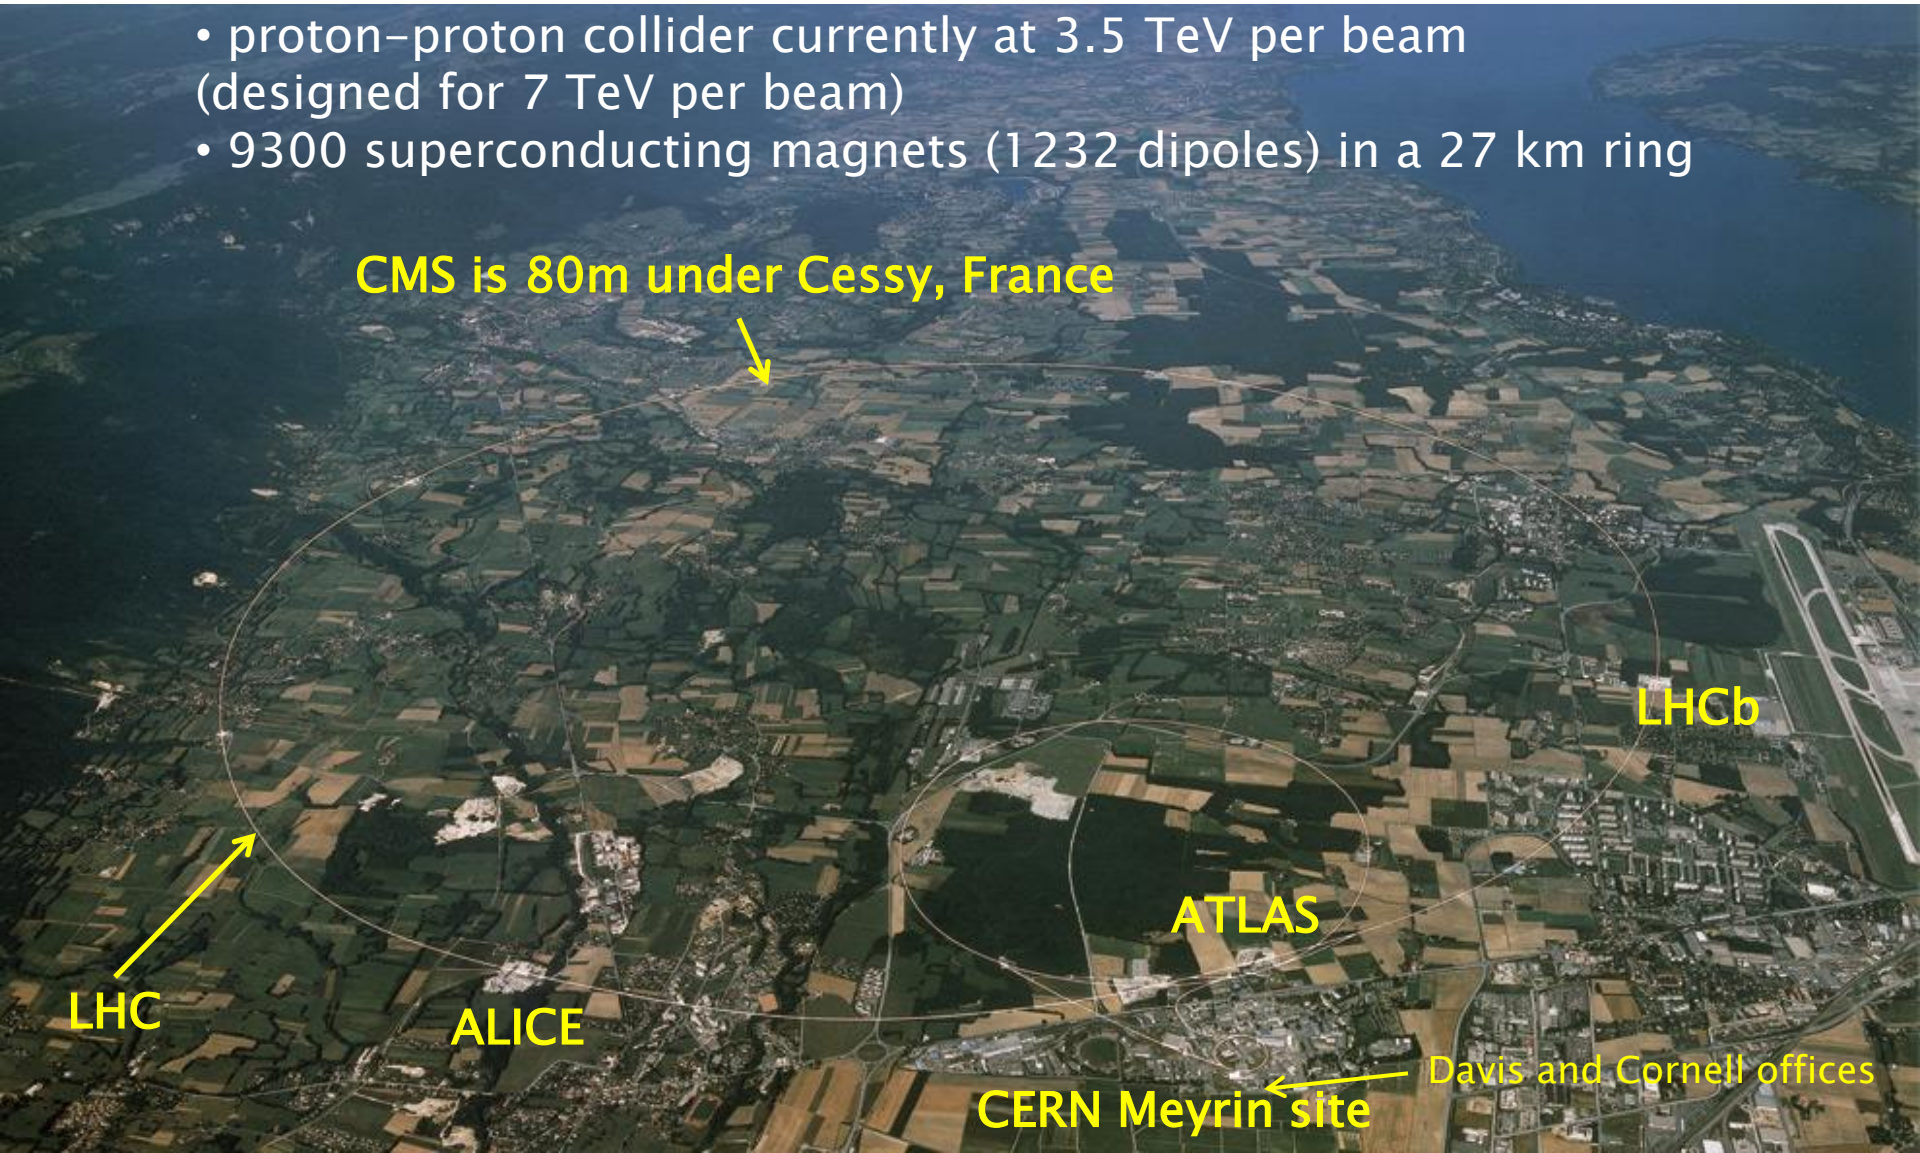

ALICE

ATLAS

LHCb

CERN Meyrin site

Davis and Cornell offices

# The CMS Detector

- 21 m long, 15 m in diameter
- 14000 tons

*CMS Collaboration:*

- ~2500 scientists + engineers
- ~850 students
- 173 institutes
- 40 countries

# A slice of CMS

J. Thompson, Cornell 26 Oct 2011

Silicon tracker:  
 $\sigma(p_T)/p_T \sim 15\%$  at 1 TeV

Electromagnetic Calorimeter (lead tungstate crystals):  
 $\sigma(E)/E \sim 3\%/\sqrt{(E) \text{ [GeV]}} \oplus 0.3\%$

Hadron calorimeter (brass + scintillator):  
 $\sigma(E)/E \sim 100\%/\sqrt{(E) \text{ [GeV]}} \oplus 5\%$

Silicon pixel detector:  
 $\sim 20\mu\text{m}$  hit resolution

- Muon
- Electron
- Charged Hadron (e.g. Pion)
- - - Neutral Hadron (e.g. Neutron)
- - - Photon

Transverse slice through CMS

Muon system (drift tubes, resistive plate chambers, cathode strip chambers):  
 $\sigma(p_T)/p_T < 1\%$  at 100 GeV  
 $\sigma(p_T)/p_T < 10\%$  at 1 TeV

JINST3:S08004 (2008)

# 2011 data-taking at CMS

- $>5 \text{ fb}^{-1}$  delivered so far
  - 2010 dataset now delivered in a few hours
- 1318 bunches colliding in CMS with 50 ns spacing
  - (design is twice as many bunches at 25 ns)
  - Very good emittance (smaller transverse beam size) and bunch intensity
  - Since Sep.,  $\beta^*$  lowered to 1.0m (smaller transverse beam size)
    - Very high pileup
      - At  $L \sim 3 \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$ ,  $\sim 15$  interactions/bunch crossing

- Recorded/delivered  $\sim 90\%$
- Good / recorded  $\sim 90\%$
- $\sim 98\%$  of the detector is working and in the readout

*Current lumi uncertainty = 4.5%*

# Why Supersymmetry?

- The Standard Model has never\* failed to describe our data, despite our best efforts
- But the observed SM + SM Higgs is not the whole story....
  - e.g. “Hierarchy problem”
    - Higgs mass receives radiative corrections due to quantum loops, proportional to the largest scale in the theory (Planck Mass,  $10^{19}$  GeV)
- SUSY adds a partner particle for each SM particle, with the same quantum numbers, except differing by  $\frac{1}{2}$  unit of spin; e.g.:
  - Spin  $\frac{1}{2}$  quarks  $\rightarrow$  spin 0 squarks ( $q\sim$ )
  - Spin 1 gluons  $\rightarrow$  spin  $\frac{1}{2}$  gluinos ( $g\sim$ )
    - This new symmetry neatly cancels the dangerous contributions to the Higgs mass

\* disregarding neutrino mass and mixing

# Signatures of SUSY

- Common to assume *R-parity conservation*
  - i.e. SUSY particles produced in pairs and always decay into another SUSY particle
    - Lightest SUSY particle (LSP) is stable
      - Good dark matter candidate
      - Escapes our detectors unseen → missing energy
- At the LHC, production dominated by gluino-gluino, squark-squark, gluino-squark
  - These are colored objects and so a lot of jets are produced when they decay
- Classic LHC SUSY signature:
  - Jets + Missing transverse energy (MET)
    - Why *transverse*?
      - remember that we don't know the initial momentum along the beamline, so we can only talk about the momentum balance in the transverse direction

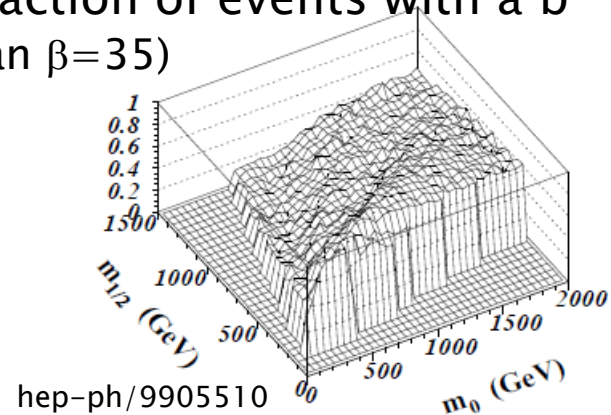

# b jets and SUSY

- Example signals:
  - Models with a light 3<sup>rd</sup> generation of sparticles ( $b\sim$ ,  $t\sim$ ), with the other squarks heavier
    - e.g.  $g\sim \rightarrow ttX\sim$
  - Models with all squarks heavy, but gluinos light
    - e.g. high  $\tan\beta$ , high  $m_0$ , low  $m_{1/2}$  in the CMSSM (like “LM9”)
    - $g\sim \rightarrow qqX\sim$  with  $q=b,t$
- Adding b-tagging also provides an experimentally complementary approach
  - Different mix of backgrounds, different systematics, etc

Mass spectrum of CMSSM test point “LM9”

Fraction of events with a b (tan  $\beta=35$ )

# Overview of backgrounds

- Signature: jets+MET+b tag
- Main background:
  - $t\bar{t} \rightarrow Wb Wb$ 
    - One W decays to hadrons
    - Other W decays to  $l\nu$ , where  $l=\tau \rightarrow \text{hadrons}$  or  $l=e,\mu,\tau \rightarrow e,\mu$  and  $e,\mu$  slips through veto
      - Neutrino provides a source of real MET
- Other backgrounds:
  - QCD
  - W+Jets
  - Z+Jets, with  $Z \rightarrow \nu\nu$

# Event selection: jets

- Expect lots of jet production from SUSY
  - Multiple hard jets
    - $\geq 4$  for MT2 analysis
      - $p_T > 20$  GeV,  $|\eta| < 2.4$
    - $\geq 3$  for MET analysis
      - $p_T > 50$  GeV,  $|\eta| < 2.4$
  - Large  $H_T = \sum_{\text{jets}} |p_T|$ 
    - $> 650$  GeV for MT2 analysis
    - $> 350$  (500) GeV for Loose (Tight) branch of MET analysis

HT > 350 GeV  
 MET > 150 GeV  
 $\geq 1$  b tag

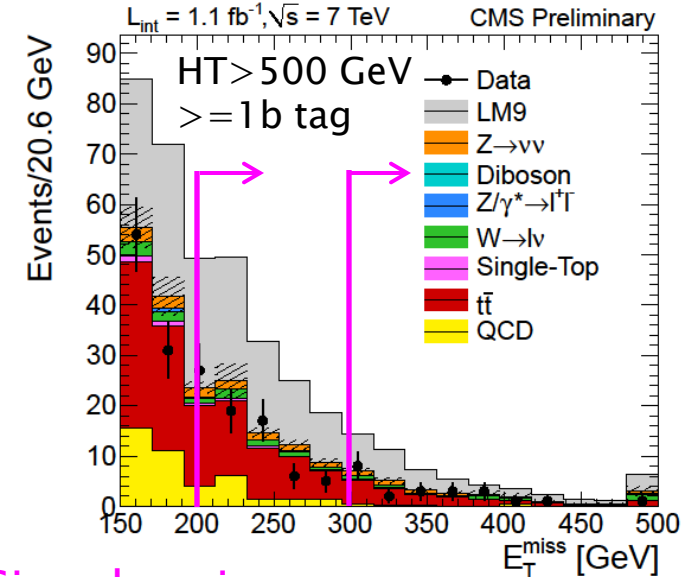

# Event selection: lepton veto

- $t\bar{t}$  is the largest background
- Reduce it by vetoing events with an isolated  $e$  or  $\mu$ , passing the following criteria:
  - $p_T > 10 \text{ GeV}$
  - $|\eta| < 2.4$  (plus veto of barrel/endcap transition for electrons)
  - Various quality and isolation requirements
- Remaining  $t\bar{t}$  events either have lepton that is outside of the selection above ( $\sim 2/3$ ), or have  $W \rightarrow \tau \rightarrow \text{hadrons}$  ( $\sim 1/3$ )

# Event selection: missing energy

- Weakly interacting particles in SUSY final state  $\rightarrow$  missing transverse energy
  - MET analysis uses MET directly
    - MET > 200 (300) for GeV for Loose (Tight)
  - MT2 analysis uses MT2
    - An extension of the transverse mass concept (commonly used for  $W \rightarrow l\nu$  decays) to decay chains with 2 unobserved particles.
    - Largely correlated with MET, but gives better rejection of non-SUSY events

$$(M_{T2})^2 = 2A_T = 2p_T^{vis(1)} p_T^{vis(2)} (1 + \cos\phi_{12})$$

Signal regions

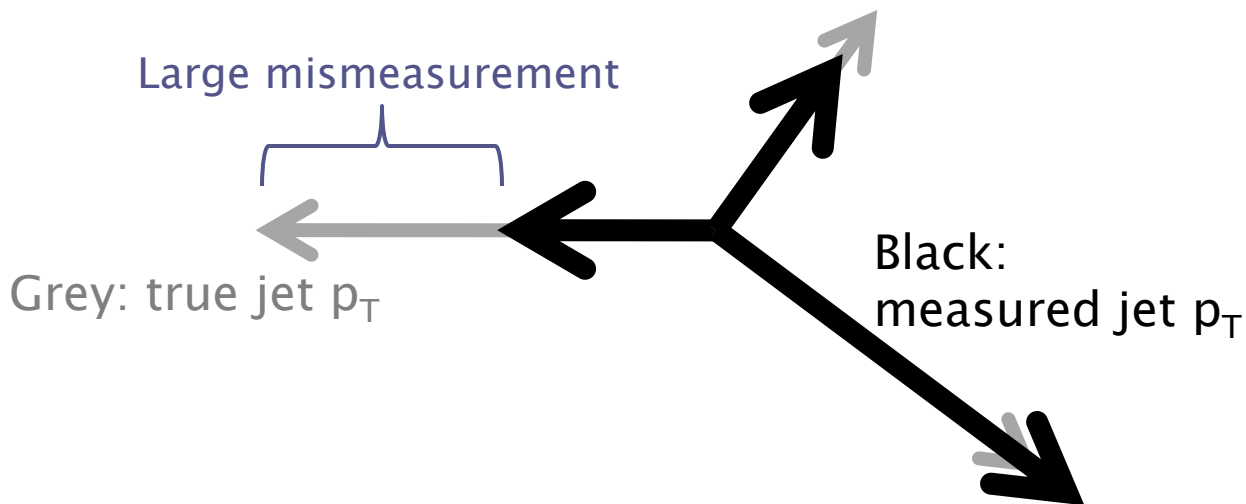

# Triggers

- How to select this signature online?
  - Use online versions of HT, missing energy
    - These calculations use calorimeter-only quantities (no “particle flow” reconstruction)
    - The missing energy calculation uses only jets (“MHT”)
- MT2+b analysis uses HT trigger
  - $HT > 550 \text{ GeV}$  (computed online)
    - Fully efficient for offline analysis HT cut
- MET+b analysis uses HT+MHT cross-trigger
  - Online thresholds:  $HT > 300 \text{ GeV}$ ,  $MHT > 80 \text{ GeV}$ 
    - Fully efficient offline  $HT > 400 \text{ GeV}$ 
      - Below plateau, correct MC for small inefficiency
    - $99 \pm 1\%$  efficient for (PF)  $MET > 200 \text{ GeV}$

*NB: I'm giving the tightest thresholds used. Earlier in the run, thresholds were lower*

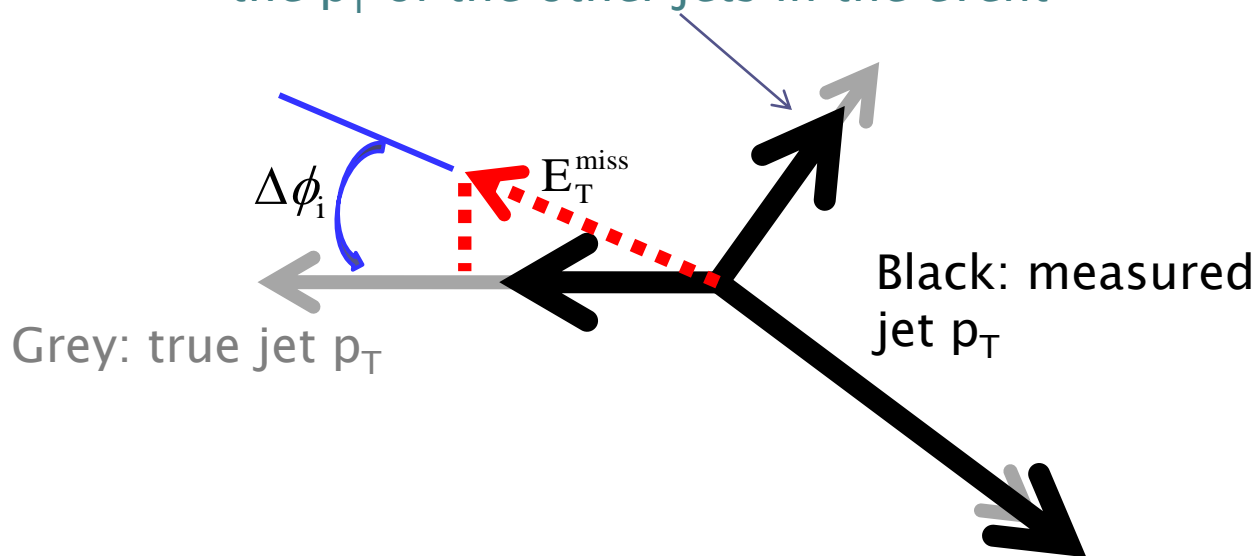

# Event selection: $\Delta\phi(\text{jet}, \text{MET})$

- QCD events can sneak into high MET region when a jet is severely mismeasured
  - Creates fake MET aligned with the jet
- Reject this background with angle  $\Delta\phi(\text{jet}, \text{MET})$ 
  - In MT2+b, require  $\Delta\phi_{\min}(\text{all jets}, \text{MET}) > 0.3$
  - In MET+b, use a slightly different variable
    - (more on the following slides)

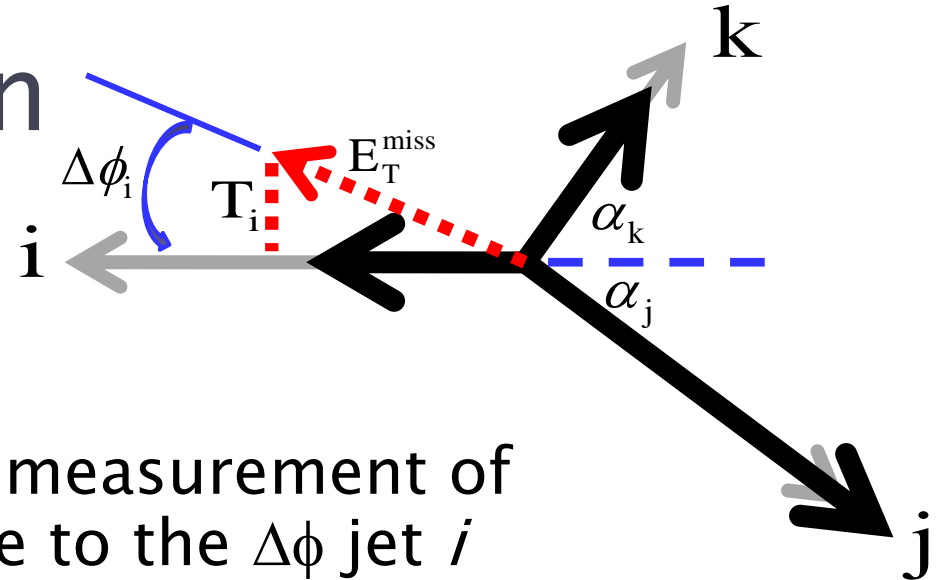

# Motivation for $\Delta\phi_N(\text{jet}, \text{MET})$

- The standard  $\Delta\phi(\text{jet}, \text{MET})$  variable is great for rejecting QCD at high MET
  - But it is also highly correlated with MET (and  $MT_2$ )
- For an event with a very badly measured jet, why is the angle  $\Delta\phi(\text{jet}, \text{MET})$  non-zero?
  - The MET direction is smeared by the small mismeasurements of the  $p_T$  of the other jets in the event

- This smearing becomes less important as the big mismeasurement (hence MET) increases  $\rightarrow$  MET and  $\Delta\phi(\text{jet}, \text{MET})$  are correlated
- we try to model this and construct an uncorrelated variable

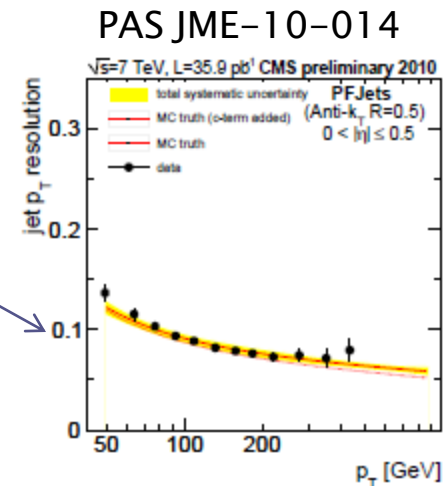

$\Delta\phi_N$  construction

- $T_i$  is the component of mismeasurement of other jets that is transverse to the  $\Delta\phi$  jet  $i$

$$T_i^2 \approx \sum_n (\sigma_{pT,n} \sin \alpha_n)^2$$

- Use 10% for jet  $p_T$  resolution  $\sigma_{pT,n}$ 
  - Cross-checks done to show we are not sensitive to this choice
- $\Delta\phi_{N,i} = \Delta\phi_i / \tan^{-1}(T_i / \text{MET})$
- This new variable is  $\Delta\phi_i$  normalized by its resolution

# $\Delta\phi$ versus $\Delta\phi_N$

- Plot the ratio of events passing the  $\Delta\phi$  cut to the ratio failing it, as a function of MET
  - This is a good way to judge the correlation
    - (flat means uncorrelated)

$\Delta\phi^{\min}, \geq 1b$

$\Delta\phi_N^{\min}, \geq 1b$

$\Delta\phi_N^{\min}, =0b$

→ pass/fail ratio for  $\Delta\phi_N^{\min}$  is ~constant for MET > ~30 GeV and independent of b tagging.

**Lends itself to a simple background estimate (discussed later)**

# Event selection: b tagging

- Both of these analyses use the Simple Secondary Vertex High Purity algorithm
  - Find a secondary vertex in a jet with at least 3 tracks
    - Make a tight selection on the discriminator value with  $\sim 50\%$  efficiency and  $\sim 0.1\%$  mistag for light jets (higher for charm)
- For signal efficiency evaluation, use data-driven scale factors to correct MC b-tag efficiency
  - $p_T < 240$  GeV: centrally provided by the CMS b-tag group
  - $240 < p_T < 350$  GeV: the MET+b analysis performed an evaluation using the ratio of double b-tagged events to single b-tagged events using a 1 lepton ( $\sim t\bar{t}$ ) control sample
    - Found scale factors to be the same, with a larger uncertainty
  - $p_T > 350$  GeV: MET+b analysis uses a scale factor of 0 for signal efficiency (conservative for a limit)
    - Not enough statistics (yet) for a proper evaluation of the scale factor in data
- Both analyses use  $\geq 1$  b tag selections
  - MET+b also uses selections with  $\geq 2$  b tags

# MC expectations in $1.1 \text{ fb}^{-1}$

- After the event selection:
  - Jet multiplicity, HT
    - Lead jet  $p_T$  in MT2 analysis
  - Lepton vetoes (e,  $\mu$ )
  - $\Delta\phi_{(N)}$  requirement
  - MT2/MET requirement

|                     | ttbar | QCD | W+jets | Z( $\nu\nu$ )+jets | Total SM | LM9  |
|---------------------|-------|-----|--------|--------------------|----------|------|
| MT2+b               | 10.8  | 0.2 | 2.2    | 1.8                | 15.0     | 42.9 |
| MET $\geq 1b$ Tight | 14.7  | 1.3 | 4.2    | 4.3                | 25.1     | 27.7 |
| MET $\geq 2b$ Loose | 28.9  | 2.5 | 1.2    | 2.2                | 35.7     | 60.0 |

*Note that MET analysis has 4 selections: (Loose, Tight) x ( $\geq 1b$ ,  $\geq 2b$ )  
The ones shown here are the most powerful for setting limits.*

# MT2 + b: background methods

- ttbar
  - Use control sample with 1 electron or 1 muon
    - Use MC efficiency numbers to move from 1 lepton  $\rightarrow$  0 lepton sample
      - Perform this method in control region  $100 < \text{MT2} < 150$  GeV
        - Compare prediction for 0 lepton sample to MC for 0 lepton sample; level of agreement quantified in the uncertainty
    - Scale from control region to signal region using MC, propagating uncertainties
- QCD
  - Extracted using a ratio of events that pass/fail  $\Delta\phi_{\min}$  selection
    - Extrapolated using a  $\exp+c$  function to model this ratio
  - Find  $0.8 \pm 0.8$  QCD events

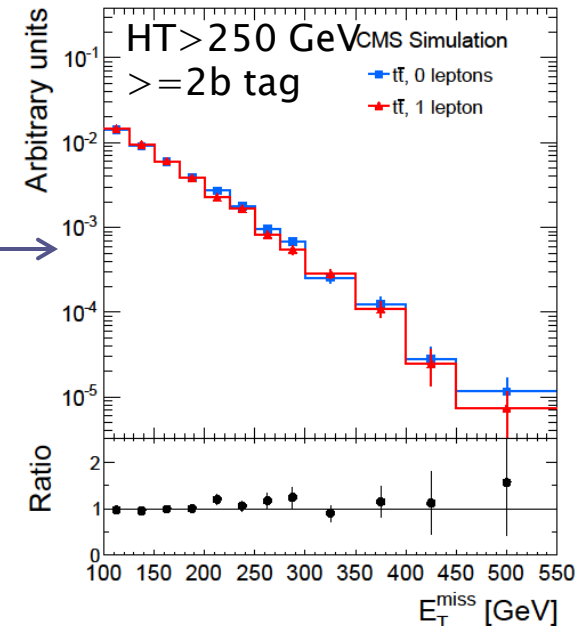

# MET+b: $t\bar{t}+W+t$ method

- MET shapes in 1 lepton sample are compatible with 0 lepton sample
- Find MET shape in 1 lepton control sample, then normalize to  $t\bar{t}$ -dominated region at medium MET ( $150 < \text{MET} < 200 \text{ GeV}$ )

$$N_{SIG}^{top+W} = \frac{N_{SIG-SL}}{N_{SB-SL}} \times \left( N_{SB} - \underbrace{N_{SB}^{Z \rightarrow \nu\bar{\nu}} - N_{SB}^{QCD} - N_{SB}^{other,MC}} \right)$$

Subtraction of contamination from other backgrounds (mostly data-driven)

*Not discussed here: independent method used as a cross-check*

# MET + b: QCD

- $\Delta\phi_N(j, \text{MET})$  variable and MET are  $\sim$ uncorrelated
  - Therefore an extrapolation can be made from low MET to high MET of the fraction of events that pass the  $\Delta\phi_N(j, \text{MET})$  selection

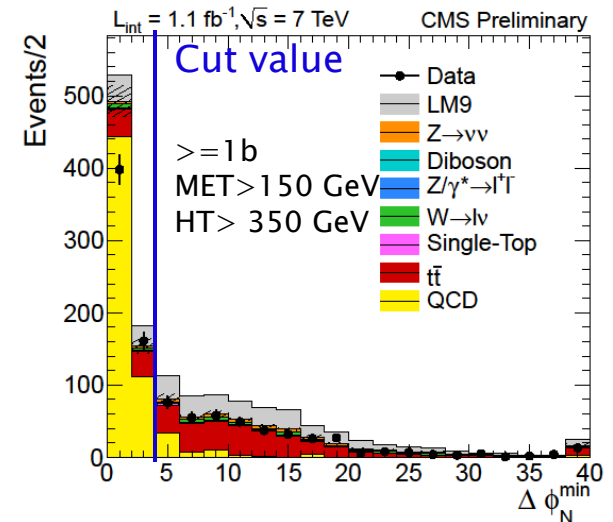

$$(N_{\text{pass}})^{\text{high MET}} = (N_{\text{pass}}/N_{\text{fail}})^{\text{low MET}} \{ (N_{\text{fail}})^{\text{high MET}} - N_{\text{contamination}} \}$$

ttbar and EW  
contamination  
taken from MC

We make this estimate in 2 different “high MET” regions:

→  $150 < \text{MET} < 200$  GeV (used in ttbar estimate)

→ Signal Region

# MET + b: $Z \rightarrow \nu\nu$ method

- Use  $Z \rightarrow ll$ ,  $l=e,\mu$  control samples
  - Treat the event as though you didn't see the leptons and you have a pseudo  $Z \rightarrow \nu\nu$  event
  - Correct for:
    - Branching ratio  $Z \rightarrow \nu\nu$  /  $Z \rightarrow ll$  = 5.95
    - efficiency to detect the leptons  $\epsilon$

$$\epsilon = \mathcal{A} \cdot \epsilon_{\ell \text{ reco}}^2 \cdot \epsilon_{\text{trig}} \cdot \epsilon_{\ell \text{ sel}}^2$$

## Efficiency factors for the leptons

Acceptance  $\mathcal{A}$ : sufficient  $p_T$ , in  $|\eta|$  range (MC)

$\epsilon_{\ell \text{ reco}}$ : reconstruction eff for leptons in the acceptance (from CMS e/ $\gamma$  group)

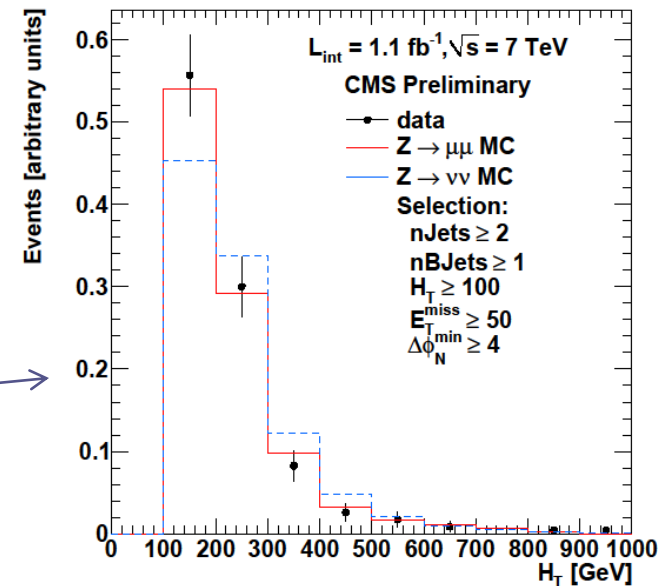

$\epsilon_{\text{trig}}$ : trigger efficiency for dilepton control samples (orthogonal trigger in data)

$\epsilon_{\ell \text{ sel}}$ : efficiency for various quality criteria added for our analysis (tag and probe in data)

# MET + b: $Z \rightarrow \nu\nu$ details

- Must determine the purity of the  $Z \rightarrow \ell\ell$  samples
  - done by fitting a Z mass peak to samples obtained with somewhat looser selection criteria
- Dilepton control samples usually have no events after the nominal MET, HT selections
  - Do estimates for looser selections, extrapolate using MC
    - MC seems to be reliable
    - Cross-check this procedure several ways, including a method that loosens the b-tagging instead of the kinematic selections
      - measure (loose b tag)/(nominal b tag) in a data control sample

# MET+b:

## Main systematics on backgrounds

- QCD
  - closure in MC
    - often driven by high-weight events in MC
    - closure was done in several ways, including a test with the MC reweighted based on the jet multiplicity distribution in data
- $t\bar{t}$ 
  - QCD subtraction
  - closure in MC
- $Z \rightarrow \nu\nu$ 
  - MC-based scaling to HT, MET tails

# Results in $1.1 \text{ fb}^{-1}$ of data

- Observed events consistent with SM background predictions

Data-driven background estimates

→JES, unclustered energy, b-tag eff, PDF are evaluated point-by-point across the CMSSM and simplified model planes

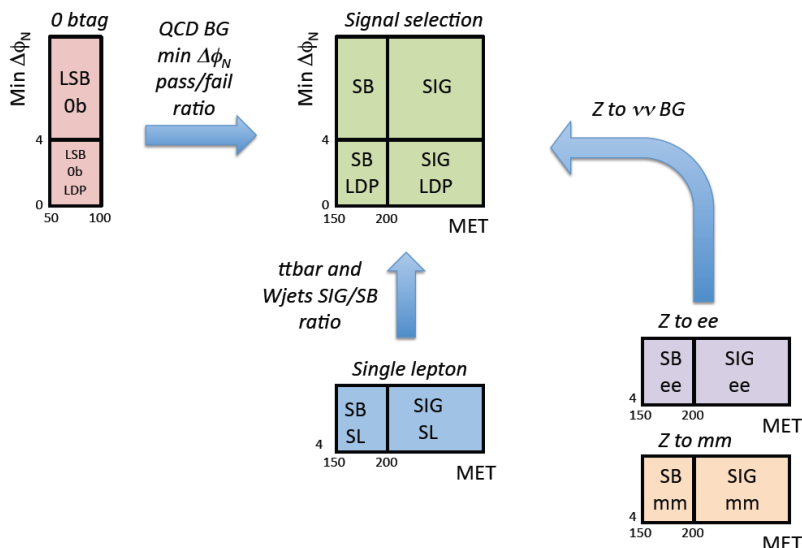

→Other uncertainties are fixed to LM9 values.

*MET+b analysis*

# Likelihood treatment (for limits)

- Combine background estimates into a RooStats framework that incorporates uncertainties and SUSY contamination
  - Event counts in data get Poisson uncertainties
    - 12 numbers total (11 control regions + signal box)
    - Note that the 5 of the control boxes can be “contaminated” by SUSY and this is treated in a consistent way in the likelihood
  - Other parameters get log normal uncertainties
  - 95% CL upper limits are evaluated using CLs tools built into RooStats

## Data observables

## Other Parameters

- systematics on the background estimation methods
  - e.g. closure test results,  $Z \rightarrow \nu\nu$  efficiency factors, ...
- statistical and systematic uncertainty on signal efficiency

# Interpretation in the CMSSM

MT2+b

MET+b

Note:  $\geq 1b$  “Tight” selection gives best *expected* limit everywhere in CMSSM, so we focus on that result

Note: MT2+b is  $\tan\beta=10$  while MET+b is  $\tan\beta=40$   
 $\rightarrow$  ignoring this difference, limits are similar

# More on MT2+b results in CMSSM

With b tag, looser MT2 cut

CMS Preliminary,  $\sqrt{s} = 7$  TeV,  $L = 1.1 \text{ fb}^{-1}$

No b tag, tighter MT2 cut

CMS Preliminary,  $\sqrt{s} = 7$  TeV,  $L = 1.1 \text{ fb}^{-1}$

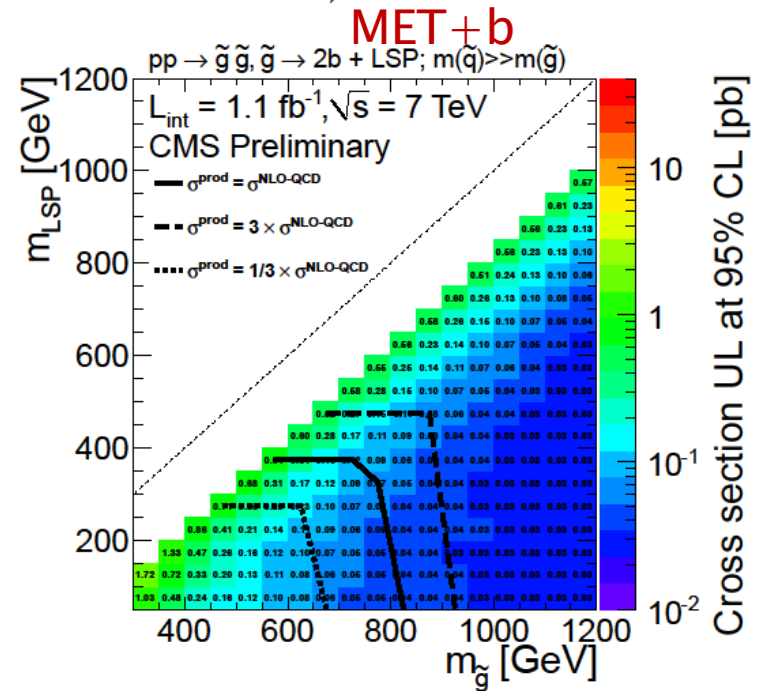

b-tagged analysis does better at high  $m_0$

→ a key advantage of b-tagged SUSY searches is that they can have looser kinematic selections while maintaining low levels of background

# Interpretation in Simplified Models

- Hard to generalize results in full models like CMSSM
  - Instead look at a simplified model, which is easier for a theorist to use when building new models
  - In our case:  $g\tilde{g} \rightarrow bbX\tilde{b}bX\tilde{b}$ 
    - Exclusive production and decay
  - Set an upper limit on the cross section as function of  $m_{g\tilde{g}}$ ,  $m_{X\tilde{b}}$ 
    - (Also get excluded region based on NLO cross section)

→ Similar sensitivity; MET + b does better in regions closer to the diagonal

# Interpretation in Simplified Models

- Note: Region very near the diagonal is very sensitive to initial state radiation (ISR).

At the moment we do not consider a systematic uncertainty due to ISR in these analyses, so we do not show results in this region.

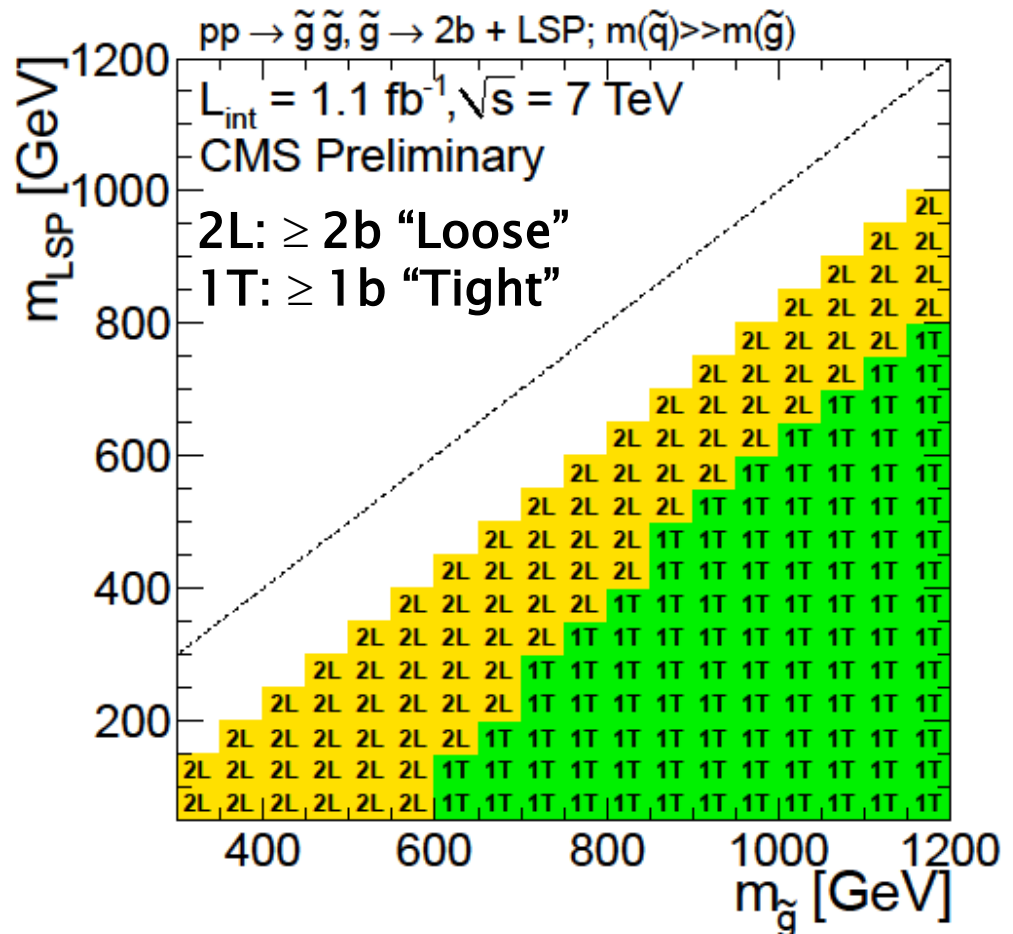

→ Similar sensitivity; MET + b does better in regions closer to the diagonal

# Note on kinematics and selections

- Simplified models have widely varying kinematics by construction
  - Heavy gluino, light LSP gives high  $p_T$  daughters  $\rightarrow$  hard jets and lots of MET
  - Nearly degenerate gluino, LSP  $\rightarrow$  soft jets and little MET
    - Challenging! Favors looser selections
- In MET+b, choose to show the limit at each point as determined by the best expected limit
  - “expected” limit is derived from data-driven background estimates, but without using the observed data counts in the signal region
  - The limit you would expect if your observed data exactly matched your background estimate

## MET+b: which selection is best

# Conclusion

- CMS has two b-tagged SUSY searches with  $1.1 \text{ fb}^{-1}$  of data
  - Expect publications with the full 2011 dataset
- Observed data consistent with background
  - Limits placed in CMSSM, 4b simplified model
    - Watch for more simplified models in the future
      - Limits on stop mass are particularly interesting...

# Highest HT event in MET+b signal region

J. Thompson, Cornell 26 Oct 2011

CMS Experiment at LHC, CERN  
Data recorded: Sun May 29 08:04:05 2011 EDT  
Run/Event: 166033 / 716123203  
Lumi section: 511  
Orbit/Crossing: 133857450 / 515

# Extra slides

# Particle flow reconstruction

- CMS makes heavy use of “particle flow” reconstruction, which combines information from the tracker, calorimeters, and muon systems to reconstruct jets, leptons, MET, etc

CMS PAS JME-10-005

MET resolution enhanced using PF reconstruction

# What is the CMSSM?

- SUSY, even in its “Minimal” MSSM variant, is rather unwieldy
  - Constrained Minimal Supersymmetric Standard Model (CMSSM) is a minimal supergravity (mSUGRA)–inspired model of soft supersymmetry breaking
    - Only 5 parameters!
      - $m_0$ : scalar mass
      - $m_{1/2}$ : universal gaugino mass
      - $A_0$ : trilinear coupling
      - $\tan \beta$ : ratio of Higgs VEVs
      - $\text{sign}(\mu)$ : sign of the Higgs mixing parameter
    - “It is a matter of some controversy whether the assumptions going into this parameterization are well–motivated on purely theoretical grounds, but from a phenomenological perspective they are clearly very nice.” – S.Martin [hep-ph/9709356v6]
      - In practice, even a 2d parameter space is tough to simulate!

# Cross-check of $t\bar{t}+W+t$ with $\Delta\theta_T$

- For  $W \rightarrow e, \mu, \tau$  ( $\tau \rightarrow e, \mu$ ) decays
  - Angular distribution of lepton w.r.t.  $W$ ,  $\Delta\theta_T$ , depends on  $W$  polarization, which is well understood
    - $\Delta\theta_T$  low  $\rightarrow$  lepton is boosted forward, neutrino goes backward  $\rightarrow$  lower MET
    - $\Delta\theta_T$  high  $\rightarrow$  lepton softer and neutrino boosted forward  $\rightarrow$  higher MET
- For  $W \rightarrow \tau$  ( $\tau \rightarrow \text{had}$ ) decays
  - Single muon control sample from  $\mu+H_T$  trigger
  - Transform muon into a  $\tau$  jet using a response template taken from MC
- For dileptonic decays
  - Dilepton control sample, scaled by an efficiency ratio taken from MC

The angle between the  $W$  pT in the lab frame, and the lepton pT in the  $W$  COM.

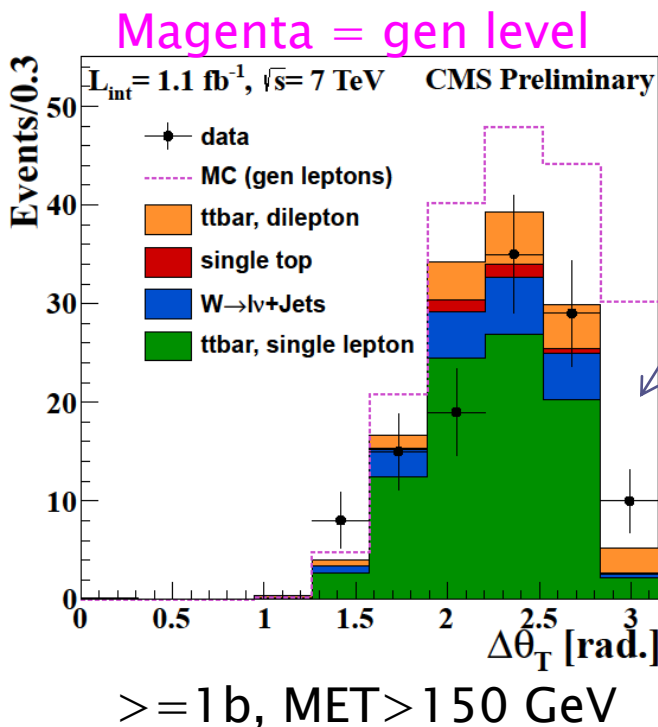

ttbar+W+t cross-check:

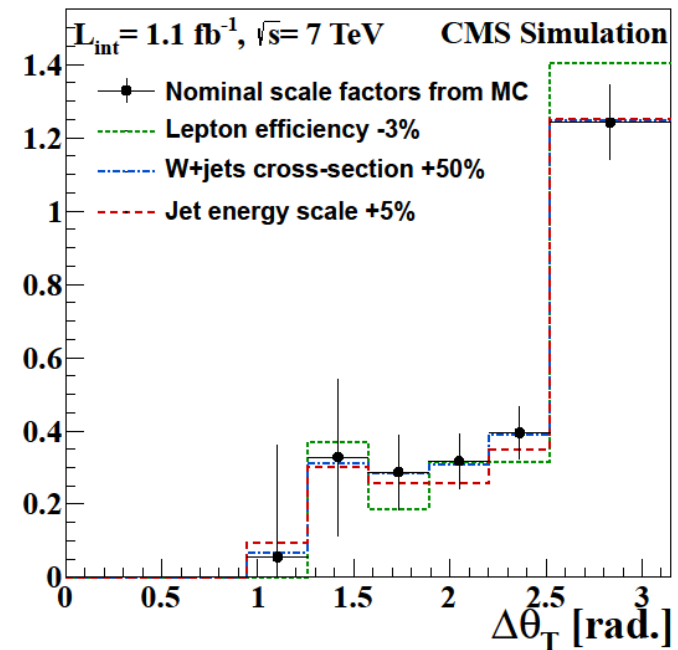

# Method for decays with e or $\mu$

- Start with single lepton control sample
- Rescale the MET distributions of the SL sample in bins of  $\Delta\theta_T$  using scale factors from MC
- Predicts both the shape and normalization of signal sample MET distribution

$$SF(\Delta\theta_T) = \frac{N_{\text{MC gen tt/W/t with 1 lost lepton}}}{N_{\text{SM MC with 1 reco lepton}}}$$

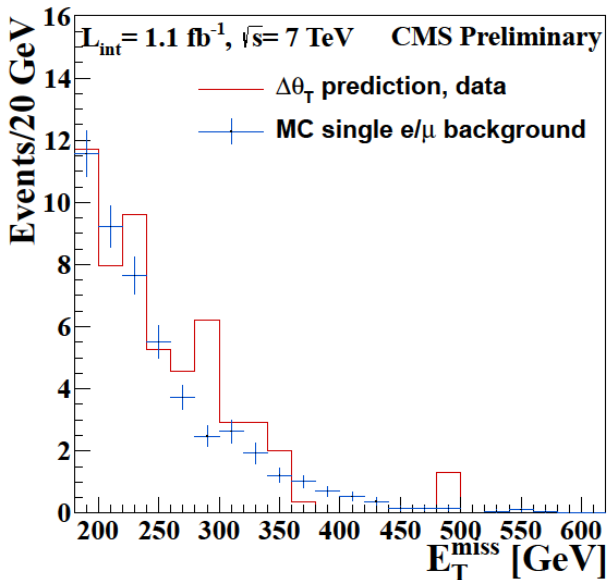

Lost leptons

# ttbar + W + t cross-check: MET spectrum predictions

$\geq 1b$ , Tight ( $HT > 500$  GeV) selection

$\Delta\theta_T$  prediction  
compared to MC shape

$\tau \rightarrow \text{had}$  prediction  
compared to MC shape

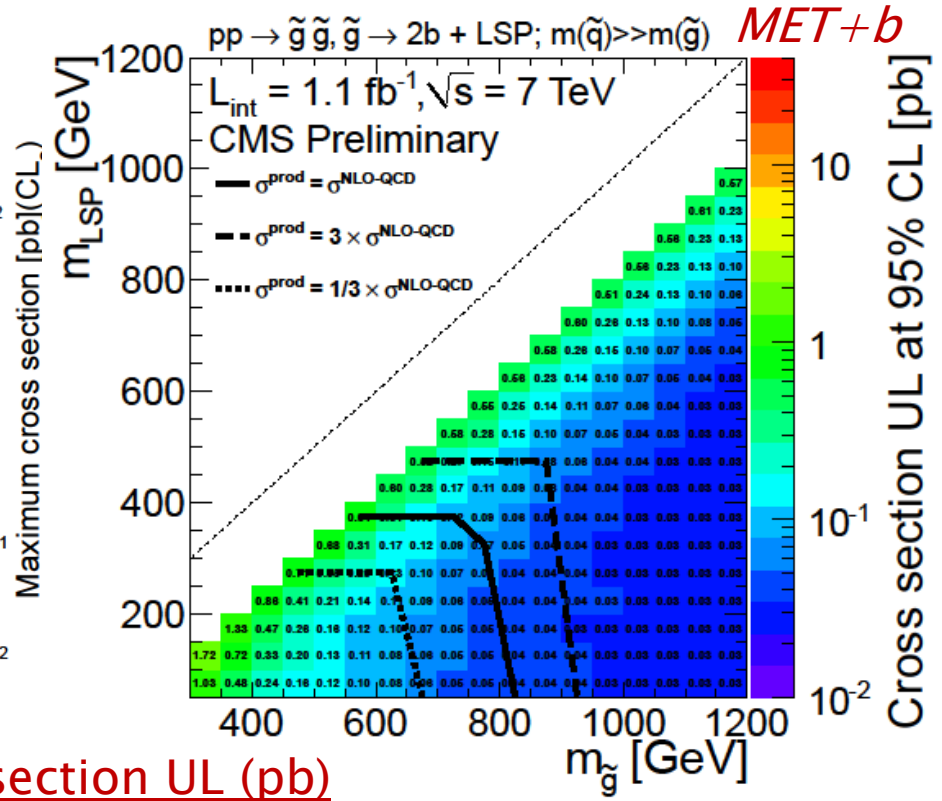

Overall prediction  
compared to data  
*NB: sizable QCD  
contribution in lowest bin*

*Note: cross-check done only for Tight selection because trigger requirements preclude doing Loose selection*

# Comparison with ATLAS

ATLAS-CONF-2011-098

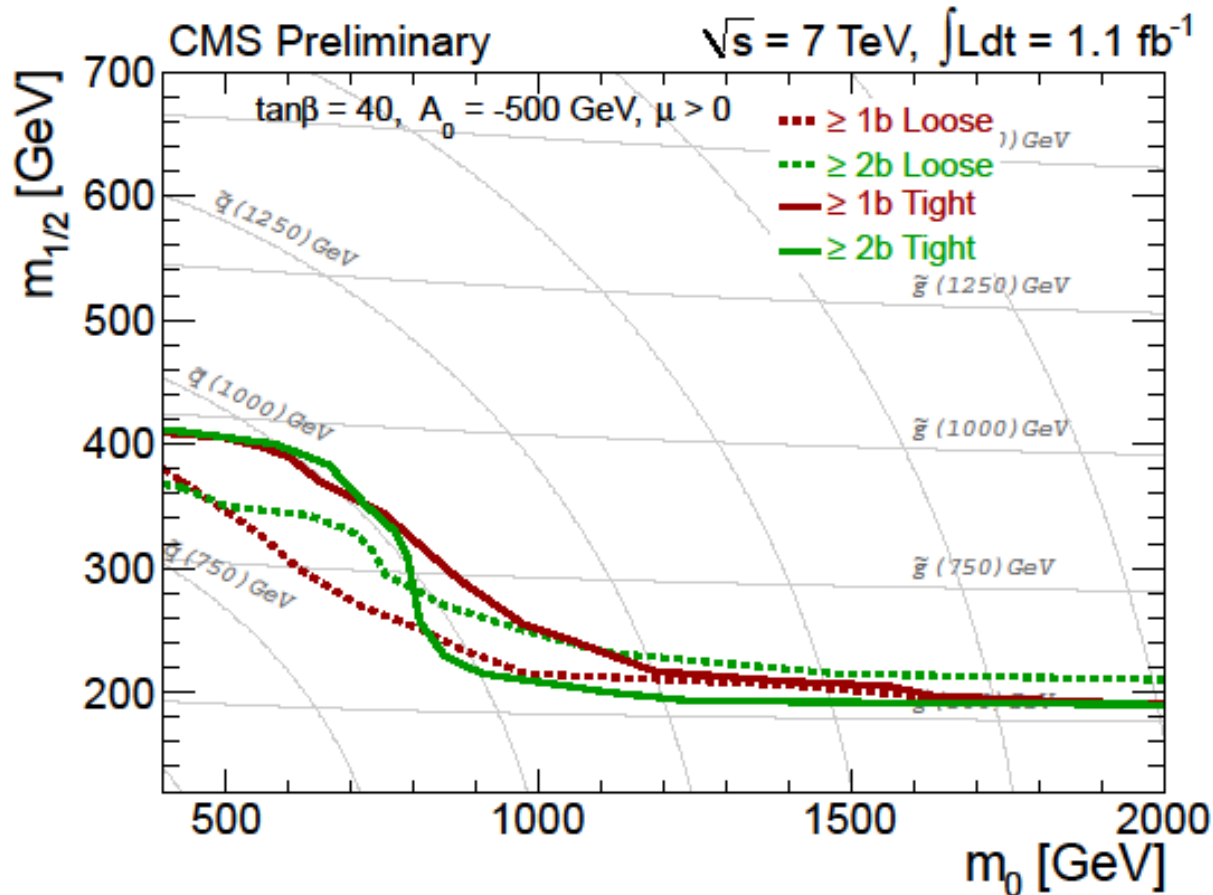

Cross section UL (pb)

| $m_{g\tilde{g}}, m_{LSP}$ (GeV) | MT2b | METb      | ATLAS |
|---------------------------------|------|-----------|-------|
| 600, 300                        | 0.60 | 0.17 (2L) | 1.0   |
| 800, 200                        | 0.08 | 0.04 (1T) | 0.5   |

(Keep in mind that CMS uses slightly more luminosity)

# Interpretation in CMSSM

- Observed limits for all four selections

95% CL exclusion  
using CLs

# MET+b: QCD systematics

## MC:

vary MC-based subtraction by  $\pm 50\%$

*[this number comes from the  $\geq 2$  b Tight case. Use it for all cases to be conservative]*

## Closure:

$1 - N_{\text{true}}/N_{\text{predicted}}$  [in quadrature with its stat error]

(use worse of raw MC and jet multiplicity-reweighted MC)

## LSB range:

vary LSB range by  $\pm 10$  GeV and take the larger observed shift  $\rightarrow$   
factor of  $>2$  change in statistics with each shift

## Systematic uncertainties in %

| Selection              | MC | Closure | LSB range | Total |
|------------------------|----|---------|-----------|-------|
| $\geq 1$ b, Loose, SB  | 10 | 28      | 2         | 30    |
| $\geq 1$ b, Loose, SIG | 29 | 102     | 2         | 106   |
| $\geq 1$ b, Tight, SB  | 8  | 71      | 10        | 72    |
| $\geq 1$ b, Tight, SIG | 73 | 213     | 10        | 225   |
| $\geq 2$ b, Loose, SB  | 21 | 69      | 2         | 72    |
| $\geq 2$ b, Loose, SIG | *  | 1156    | *         | *     |
| $\geq 2$ b, Tight, SB  | 19 | 199     | 10        | 200   |
| $\geq 2$ b, Tight, SIG | 34 | 370     | 10        | 371   |

***NB on  $\geq 2$ , Loose, SIG:***  
*Large systematic stems from large stat error on  $N_{\text{true}}$  in MC*  
*\* reflects the fact that the nominal value is 0, so a % change is ill-defined.*

# MET + b: $Z \rightarrow \nu\nu$ systematics

- Background subtraction:
  - From the stat uncertainty in the fits to the Z peak
- MC closure:
  - Full lack of closure taken as a systematic
- MC extrapolation:
  - 50% for MC scale factor  $>0.1$ ; 100% for MC scale factor  $<0.1$ 
    - These numbers are justified by the spread seen in the cross-checks

Table 7: Systematic uncertainties for the  $Z \rightarrow \nu\bar{\nu}$  background estimate.

| Contribution                              | size (%)                   |                        |
|---|----------------------------|------------------------|
|   | $Z \rightarrow \mu^+\mu^-$ | $Z \rightarrow e^+e^-$ |
| Background subtraction                    | 18                         | 20                     |
| Acceptance                                | 2                          | 2                      |
| Trigger efficiency                        | 3                          | 3                      |
| Lepton selection efficiency               | 5                          | 5                      |
| MC closure                                | 19                         | 11                     |
| MC extrapolation                          | 0 – 100                    | 0 – 100                |
| Total without extrapolation               | 27                         | 24                     |
| Total with 50% extrapolation uncertainty  | 57                         | 55                     |
| Total with 100% extrapolation uncertainty | 104                        | 103                    |

# MET+b:

## ttbar systematic uncertainties

- Closure systematic taken from worse (for each selection independently) of ttbar+W+t closure test and ttbar-only closure test
- Data-driven subtractions varied by their errors
- Small MC-driven subtraction varied by  $\pm 100\%$

%

| Selection         | Contamination subtraction |     |                              |       | Total |
