# The main questions

- Is the particle discovered by CMS and ATLAS, the SM Higgs?
  
- Do the present data allow any scope for BSM effects?

# What's new in our work

- 7-parameter global fit presented.
- Different coupling modifications to  $W$  and  $Z$  bosons allowed.
- Different coupling modifications to  $u$ -type and  $d$ -type quarks allowed.
- Arbitrary phase in the top-quark coupling allowed.
- Invisible decay width of Higgs allowed.
- Additional states allowed in  $Hgg$  and  $H\gamma\gamma$  couplings.

## Parametrization of new physics effects

- **Fermion Couplings** : Classifying all  $T_3 = +1/2$  fermions as u and all  $T_3 = -1/2$  fermions as d, we assume

$$\mathcal{L}_{H\bar{u}u} = e^{i\delta} \alpha_u \frac{m_u}{v} H\bar{u}u$$

$$\mathcal{L}_{H\bar{d}d} = \alpha_d \frac{m_d}{v} H\bar{d}d$$

- **Gauge boson pair couplings** : We parametrize the interactions of the observed scalar to a pair of weak gauge bosons as

$$\mathcal{L}_{HWW} = \beta_W \frac{2m_W^2}{v} HW_\mu^+ W^{\mu-}$$

$$\mathcal{L}_{HZZ} = \beta_Z \frac{m_Z^2}{v} HZ_\mu Z^\mu$$

# Parametrization of new physics effects

- **Effective gluon-gluon and photon-photon couplings** : We parametrize the gluon-gluon-Higgs and Higgs-photon-photon amplitudes as follows :

$$\mathcal{L}_{gg} = -x_g f(\alpha_u) \frac{\alpha_s}{12\pi v} H G_{\mu\nu}^a G^{a\mu\nu}$$

$$\mathcal{L}_{\gamma\gamma} = -x_\gamma g(\alpha_u, \alpha_d, \beta_W, \delta) \frac{\alpha_{em}}{8\pi v} H F_{\mu\nu} F^{\mu\nu}$$

- **Invisible width** : Earlier studies have given different conclusions about a possible invisible decay width of Higgs. Here we parametrize it as :

$$\Gamma_{inv} = \frac{\epsilon}{1 - \epsilon} \sum \Gamma_{vis}$$

where  $\epsilon$  is the invisible branching fraction.

# Methodology

- Experimental collaborations have reported various observed signal strengths in the  $i^{\text{th}}$  channel in terms of  $\hat{\mu}_i = \sigma_i^{\text{obs}} / \sigma_i^{\text{SM}}$ .
  - $\sigma_i^{\text{obs}}$  : observed signal cross-section for a particular Higgs mass.
  - $\sigma_i^{\text{SM}}$  : signal cross-section for an SM Higgs with the same mass.
- We calculate  $\mu_i$  for various points in the space spanned by the parameters.
- We can express  $\mu_i$  as

$$\mu_i = R_i^{\text{prod}} \times R_i^{\text{decay}} / R^{\text{width}}$$

- We consider latest results from CMS and ATLAS and available results from Tevatron.
- The following decay channels are considered in our analysis :  $\gamma\gamma(\text{inclusive})$ ,  $ZZ^* \rightarrow 4l$ ,  $WW^* \rightarrow ll\nu\nu$ ,  $\tau^+\tau^-$ ,  $b\bar{b}$ ,  $\gamma\gamma jj$ .

## Best-fit values of parameters

$\chi^2$  analysis was performed to obtain the best-fit values of the different parameters.

Case	$\beta_W$	$\beta_Z$	$\alpha_u$	$\alpha_d$	$x_g$	$x_\gamma$	$\epsilon$	$\delta$
A	1.3	1.4	-0.66	-1.2	1.6	1.0	0.4	0*
B	1.15	1.15	-1.48	1.04	0.6	0.9	0.1	1.0
C	1.07	1.07	-0.27	0.97	3.1	1.0	0.02	0*

**Table:** Best-fit values of the various parameters in the three cases considered. In cases A and C,  $\delta$  has been fixed at 0 (indicated with a '\*'). In cases B and C, the relation  $\beta_W = \beta_Z$  has been imposed, and their values have been restricted within precision constraints.

## Contour Plots (Case A)

**Figure:** Two-dimensional contour plots for 68% and 95% confidence intervals, for case A, with rest of the parameters fixed at their best-fit values. The best-fit point is also marked separately by a '\*'. In this case  $\delta$  has been fixed at 0, whereas  $0 \leq \beta_W, \beta_Z \leq 2.0$ , and  $\beta_W \neq \beta_Z$ .

## Contour Plots (Case B)

**Figure:** Two-dimensional contour plots for 68% and 95% confidence intervals, for case B, with rest of the parameters fixed at their best-fit values. The best-fit point is also marked separately by a '\*'. In this case  $\delta$  has been varied in the range  $\{0, \pi\}$ , whereas  $0.92 \leq \beta \leq 1.18$ , with  $\beta \equiv \beta_W = \beta_Z$ .

## $\chi^2$ vs $\epsilon$ plots

Figure: Variation of the  $\chi^2$  function with the invisible branching fraction of  $H$  ( $\epsilon$ ) in case A ( $\delta = 0$  and  $\beta_W \neq \beta_Z$ ).

## $\chi^2$ vs $\delta$ plot

**Figure:** Variation of the  $\chi^2$  function with the phase in the up-type quark Yukawa coupling,  $\delta$ , in case B. In this case  $\delta$  has been varied in the range  $\{0, \pi\}$ , whereas  $0.92 \leq \beta \leq 1.18$ , with  $\beta \equiv \beta_W = \beta_Z$ .

# Conclusions

- Fermiophobic Higgs is by and large disfavoured.
- Non-trivial phase in top-quark coupling play an important role. Can be as large as  $\frac{4}{5}\pi$  radians at 68% confidence interval.
- Hint of relative sign between  $\alpha_u$  and  $\beta_W$ .
- Hint of an invisible decay width of Higgs. Can be as large as 60% (Case A) and 45% (Case B) at 68% confidence interval.
- Given the present data, substantial departure from SM couplings are allowed.

## Marginalisation - Backup

**Figure:** Two-dimensional marginalised contour plots for 68% confidence intervals, for case A. The best-fit point is also marked separately by a '\*'. In this case  $\delta$  has been fixed at 0, whereas  $0 \leq \beta_W, \beta_Z \leq 2.0$ , and  $\beta_W \neq \beta_Z$ . This is based on the data published on 4th July and before.
