

# ITS upgrade meeting

---

“Improvements to chapter 3 of CDR within the next 3 weeks”

G.E. Bruno

**Outline:**

- remind of the time-line
- possible improvements

# Timescale

- **CDR v1.0** to ITS Collaboration and IRC: ITS Upgrade Plenary Meeting on 14<sup>th</sup> November (**today**)
  - **CDR v2.0** + executive summary (including comments from IRC and ITS) to ALICE: **5<sup>th</sup> December**
  - presentation of upgrade projects to ALICE: during the 12<sup>th</sup> December mini-week (joint session of TB/PB)
- we have 3 weeks to improve the CDR from present **v1.0** to **v2.0**:
- obviously, comments from you and IRC
  - are there substantial modifications that can be done in the timescale of the next 3 weeks ?

1. Remove upgrade scenario 1 (NEW-SPD)
2. PID reviewed against realistic technical implementations
3. Performance of combined tracking ITS +TRD
4. Requirements for single track time resolution
5. Include a detector performance study for layer0 with 0.1% radiation length

# 1. Remove upgrade scenario 1 (NEW-SPD)

---

- Reasons:

1. life-time of new detector should span over several years

2. running scenario being defined now within the ALICE Upgrade Task Force:

- interaction rate:

- **Pb-Pb at 50 KHz**
- Ar-Ar at 140 KHz
- pp at 2MHz

## 2. PID reviewed against realistic technical implementations

---

- Reasons:
  - development of PID study done in parallel with the study and definition of the “best” layouts for tracking performance
  - few configurations discussed in sec. 3.7, one is ideal (w.r.t. the technical implementation), none of them corresponds to those defined from the tracking study (SPD-New and ALL-New)
- Actions:
  - define 1 or 2 different configurations (Vito & Luciano) and repeat the study for that (Francesco, Stefano, Stefania)
- dead-line: 2 weeks
- General comments: no strong links to the physics performance
  - difficult to improve within 3 weeks

# 3. Performance of combined tracking ITS+TRD

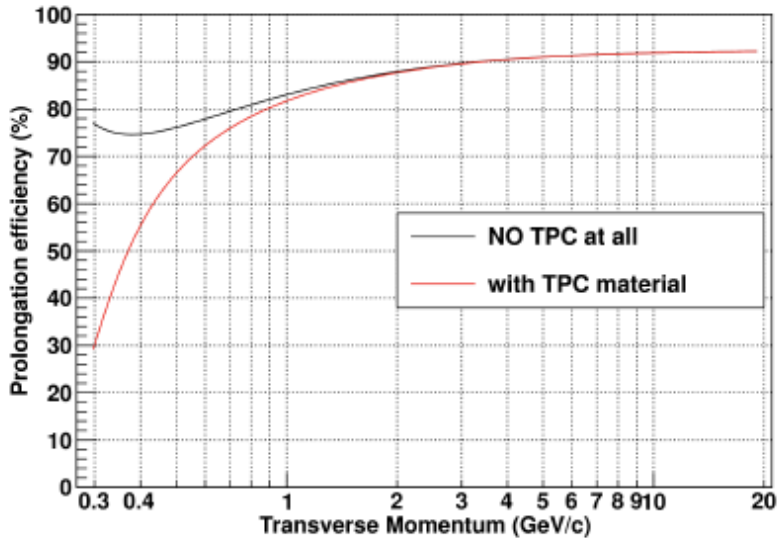

- Reasons: exploit the Pb-Pb 50 KHz running scenario
  - ITS+TRD tracking → TOF (for PID)
- Actions: Stefan is studying it

First glance of the “matching probability” in outward direction ...  
 (obtained with Fast-Tool, central PbPb)

Stefan

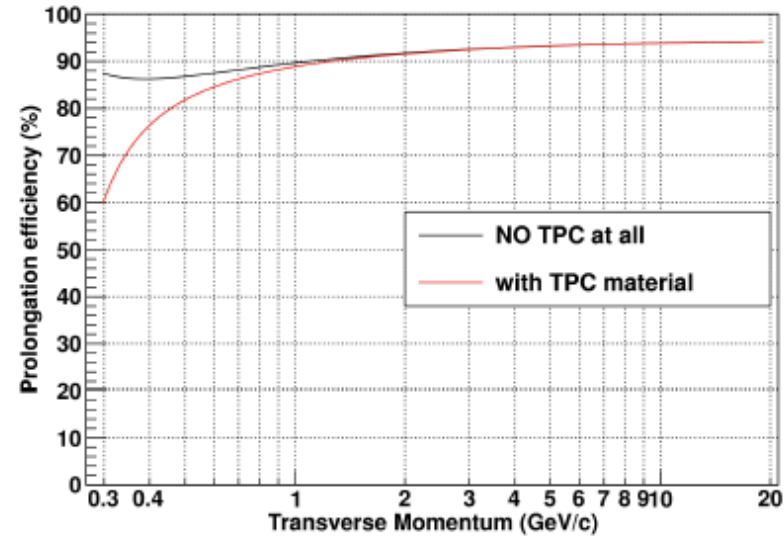

*Current ITS configuration*

Prolongation efficiency onto layer "trd1"

*All-New configuration*

Prolongation efficiency onto layer "trd1"

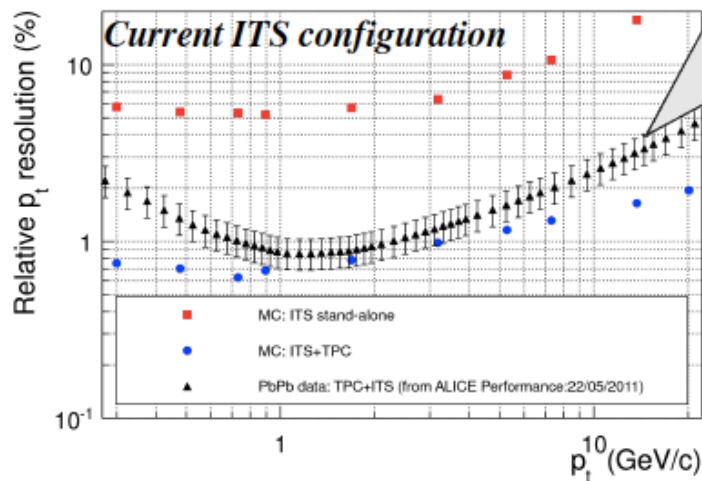

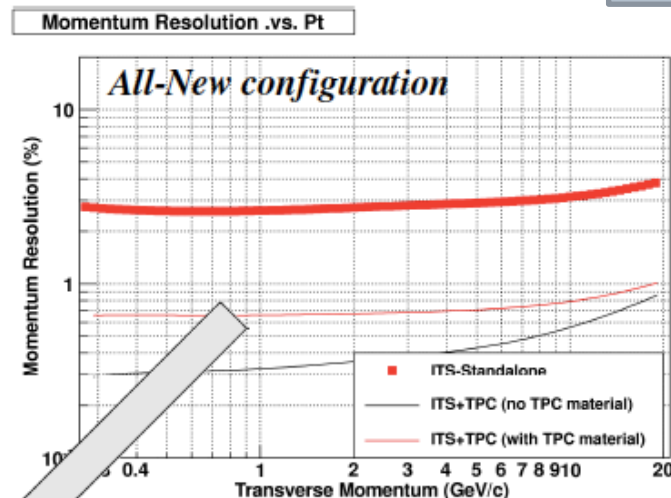

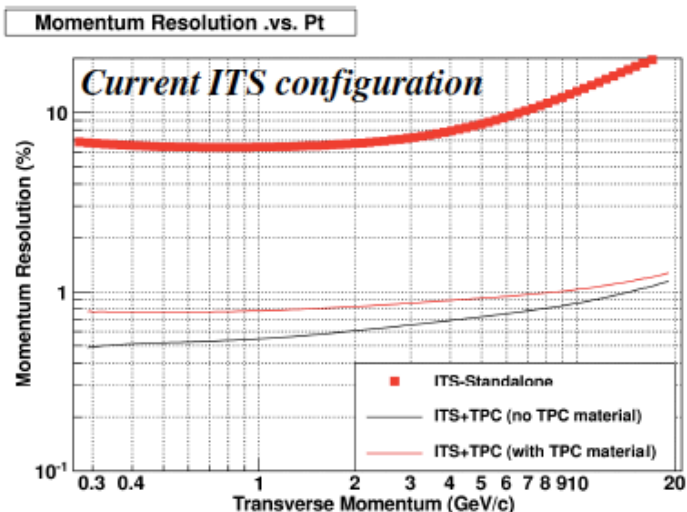

Lower pt limit around 300 MeV (outermost TRD layer at r~360cm)

## 2) Combined ITS plus TRD tracking

First glance of the “improved pt resolution” (with “ideal TRD”) ...

Stefan

Assuming that the “matching” works sufficiently well ...

→ ITS+TRD pt resolution might be better than current ITS+TPC performance due to the longer lever arm

→ This of course assumes an “ideal TRD (and ITS)”

## 3) Single track time-resolution

Ruben

(thanks to discussions with Magnus)

- Depends of course on the “expected” IR and and the integration time

Probability for PileUp?

$$P = 1 - \text{Exp}(-\lambda\tau)$$

$\lambda = \text{IR}$ ;  $\tau = \text{integration time}$

$\lambda/\tau$	0.1 $\mu\text{s}$	1 $\mu\text{s}$	20 $\mu\text{s}$	50 $\mu\text{s}$
8kHz	0.08%	0.8%	14.8%	33.0%
50kHz	0.5%	4.9%	63.2%	91.8%

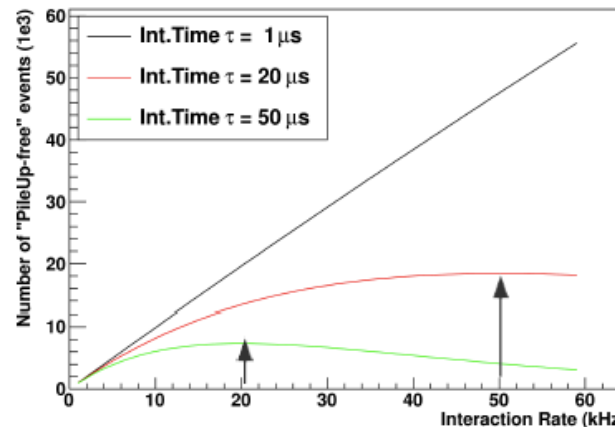

Mean number of Piled-Up event

$$N = \lambda\tau$$

$\lambda/\tau$	0.1 $\mu\text{s}$	1 $\mu\text{s}$	20 $\mu\text{s}$	50 $\mu\text{s}$
8kHz	< 0.1	< 0.1	0.16	0.4
50kHz	< 0.1	< 0.1	1	2.5

- Optimum on “recorded events” (PileUp free), “read-out” time is not considered

→ less than 1  $\mu\text{s}$  is a “save choice”

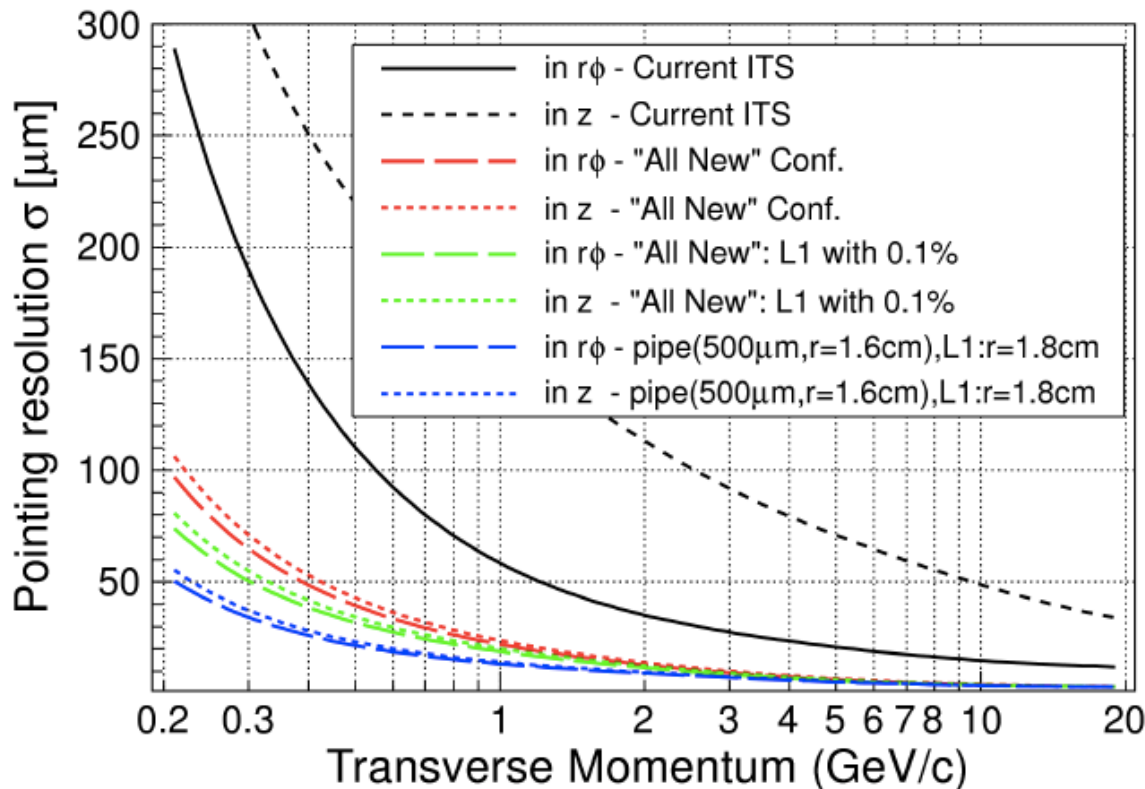

# 5. Include a study for layer0 with 0.1% radiation length

## 1) Further improvement of the Impact-Parameter Resolution

To reach another factor 2 in comparison to the "ALL-NEW" setup, we not only have improve the properties of the first Layer, but also of the beam-pipe ...

→ This is an other unrepresented challenge ... ;-)

Add. factor 2 means:

**L1:**

**X0: 0.3% → 0.1%**

**R = 2.2 cm → 1.8 cm**

**Beam-pipe:**

**Width: 800 → 500  $\mu$ m**

**R = 2.0 cm → 1.6 cm**

$\Lambda_c$  studies will show if we need the additional Factor 2?

# Conclusion

---

- we would appreciate your feedback to improve the document

Extras

## 3) Single track time-resolution

Ruben

BUT, the problem is two-fold:

a) At least two (inner) layers should be able to distinguish between two events (including trigger-information?)

→ Integration time  $< 1\mu\text{s}$  ?

b) As long as the other layers do not pile-up too many events, the reconstruction efficiency should not suffer too much?
