Recent BaBar limits on new physics

We present recent BaBar results on two types of new-physics searches. The first type is direct searches for low-mass dark gauge bosons and dark Higgs, motivated by theories developed to explain recent astrophysical anomalies. The second type involves B-meson decays with final states containing neutrinos, where full-event reconstruction is used to measure the 4-momentum of the neutrinos and suppress background. This includes a search for lepton-number violation in $B \rightarrow K \tau l$ and $B \rightarrow \pi \tau l$, and searches for flavor-changing neutral-current B decays into final states with neutrinos.
