Searches for SUSY in hadronic final states at CMS

Riccardo Bellan
UCSB

On behalf of the CMS Collaboration

Physics at LHC – 2012, UBC Vancouver
Introduction - Phenomenology

Under the assumptions of a parity conservation (e.g. R-parity), a lightest stable particle (LSP) is present in the theory. All Sparticles eventually decay into the LSP. These escape the detector without interacting.

- **Missing transverse momentum**
- **Good dark matter candidate**

⇒ **Key Signature: multi-jets + missing transverse momentum + X**
Analyses going to be presented

Results from Hadronic and Photon(s) + missing transverse momentum analyses using the **full 2011 dataset at 7 TeV**

- **Search for Supersymmetry in hadronic final states using $M_{T2}$ with the CMS detector at 7 TeV**
  - PAS-SUS-12-002, 4.73/fb.

- **Search for new physics in the multijets + missing transverse energy final state**
  - PAS-SUS-12-011, 4.98/fb.

- **Search for supersymmetry with the razor variables at $\sqrt{s} = 7$ TeV**
  - PAS-SUS-12-005, 4.4/fb.

- **Search for supersymmetry in events with photons and missing energy**
  - PAS-SUS-12-001, 4.7/fb.

*CMS SUSY public results can be found at this link*
https://twiki.cern.ch/twiki/bin/view/CMSPublic/PhysicsResultsSUS
The analysis is based on $M_{T2}$, which is a generalization of the transverse mass for decay chains with two unobserved particles, as typical in SUSY events.

$$M_{T2} = \min_{p_T^c = 0} \left[ \max \left( m_T^{(1)}, m_T^{(2)} \right) \right] \approx ME_T,$$

for SUSY events

$M_{T2}$ is a QCD killer ($M_{T2} \approx 0$ for back-to-back events with no genuine $ME_T$) and provides a very good discriminating power between SM and SUSY-like events in combination with $H_T$ (scalar sum of all $p_T^{jets}$ in the event) cut.

Two analyses based on the same background estimation techniques and are aiming to cover complementary SUSY topologies

- $M_{T2}$
  - 2 $H_T$ bins and 5 $M_{T2}$ bins
  - $\geq 3$ central jets (40 GeV), $\Delta \phi_{min} (ME_T^{jets}) > 0.3$
  - $W \to jets$ and $Z \to \nu \nu$ are main backgrounds
  - Optimized for signal w/ large $ME_T$ (low $m_0$)

- $M_{T2}$-b ($\geq 1$ b-tagged jet)
  - 2 $H_T$ bins and 4 $M_{T2}$ bins (lower thresholds)
  - $\geq 4$ central jets, $\Delta \phi_{min} (ME_T^{jet}) > 0.3$
  - $ttbar$ is the main background
  - Optimized for light gluino decaying to 3$^{rd}$ generation squarks (high $m_0$)
$M_{T2}$ Background Estimation

QCD

Predict signal region (high $M_{T2}$, $\Delta\phi_{\text{min}} > 0.3$) from QCD enhanced region (high $M_{T2}$, $\Delta\phi_{\text{min}} < 0.2$) using an exponential form with parameters from a fit in the region $50 < M_{T2} < 80$ GeV

$Z \rightarrow \nu\nu$

Prediction is taken as the weighted average of $Z \rightarrow \nu\nu$ from $W \rightarrow \mu\nu$ and from $\gamma + \text{jets}$ estimations, which exploit similarities in the $V+\text{jets}$ processes

$$N_{Z\nu\nu} = N_{W\mu\nu} \cdot \frac{1}{\epsilon_{\text{acc}}\epsilon_{\text{iso}}} \cdot R^{\text{MC}}$$

$ttbar/W \rightarrow l\nu$

Largely reduced by lepton veto. Remaining is from $e$ or $\mu$ out of acceptance or not identified, and hadronic $\tau$-decays

Estimated from electron and muon samples ("hadronic" $\tau$ from MC)

$$N_{e,\mu}^{\text{lost lepton}} = (N_{e,\mu}^{\text{data}} - N_{e,\mu}^{\text{bg}}) \cdot \frac{1 - \epsilon_{e,\mu}}{\epsilon_{e,\mu}}$$
MT2-b Background Estimation

QCD

Predict signal region (high MT2, Δφ_{min} > 0.3) from QCD enhanced region (high MT2, Δφ_{min} < 0.2) using an exponential form with parameters from a fit in the region 50 < MT2 < 80 GeV

Z → νν

Prediction is taken from Z → νν estimated from W → μν, which exploit similarities in the V+jets processes

\[ N_{Z\nu\nu} = N_{W\mu\nu} \cdot \frac{1}{\varepsilon_{acc} \varepsilon_{roco/iso}} \cdot R^{MC} \]

ttbar/W → lν

Largely reduced by lepton veto. Remaining is from e or μ out of acceptance or not identified, and hadronic τ-decays

Estimated from electron and muon samples ("hadronic" τ from MC)

\[ N_{e,\mu}^{\text{lost leptons}} = (N_{e,\mu}^{\text{acc}} - N_{e,\mu}^{bg}) \cdot \frac{1 - \varepsilon_{e,\mu}}{\varepsilon_{e,\mu}} \]
No significant excess observed in data, we proceed by setting upper limits using CLs.

- $M_{T2}$- and $M_{T2}$-b analyses are not orthogonal, they are not statistically combined, the best limit is used for the final result.

Effects taken into account bin by bin, point by point:

- Signal contamination in leptonic control sample
- Theory uncertainties on PDF and factorization and renormalization scale
- Jet energy scale uncertainty introduced as a nuisance parameter on signal model.
- B-tagging uncertainties introduced as a nuisance parameter on signal model.
- Luminosity uncertainty
Limits from $M_{T2}$ On Simplified Models

CMS Preliminary, $\sqrt{s} = 7$ TeV, $L = 4.73$ fb$^{-1}$

- $pp \rightarrow \tilde{g}\tilde{g} \rightarrow 2q + \tilde{\chi}^0$; $m(\tilde{g}) \gg m(\tilde{\chi}^0)$

Multi-jets + MH$_T$ Analysis

Inclusive analysis in the jets + missing transverse momentum final state, aimed to **fully characterise** the event's kinematic in the search regions

**Based on:**

\[ H_T = \sum_i p_T^i , \] visible-energy scale

\[ \bar{H}_T = -\sum_i p_T^i , \] Undetected particle energy scale

- At least 3 jets with $p_T > 50$ GeV and $|\eta| < 2.5$, with isolated-lepton veto

**Requirements:**

- $\Delta\phi$(MH$_T$-jet$_i$) > .5, .5, .3, $j = 1^{st}$, $2^{nd}$, $3^{rd}$ most energetic jets

- $H_T > 500$ GeV and MH$_T > 200$ GeV, then **14 exclusive H$_T$,MH$_T$ bins**
Jets+$MHT_T$ Background Estimation

QCD: Rebalance and Smearing

- **Rebalance**: Particle level $p_T$ is restored from detector level inclusive multijet data using a kinematic fit subject to constraint $MHT +$ soft particle $= 0$ (using jet resolution functions derived from MC but corrected to match data)

- **Smear**: events are then smeared using the measured jet resolution functions including non-Gaussian tails

- Obtain a data driven estimation of full kinematics of QCD multijet events
  - predict HT, MHT, angles between jets and MHT

**ttbar/W → lν, lost lepton**

- Similarly as in $M_{T2}$ analysis, it is estimated from electron and muon samples, correcting back for lepton isolation and id efficiencies

**Hadronic tau decays from top/W → τν**

- Estimated from data using a muon control sample and a $\tau$ detector-response template used to smear the muon momentum

**$Z → νν$**

- Estimated using $γ+jets$ sample (validated w/ prediction from $Z → μμ$) exploiting the commonalities of the processes with production of $γ$ and $Z$

$$N_{Z→νν+jet} = \left( \frac{Z \rightarrow νγ + jet}{γ + jet} \right)_{mc} \times \epsilon^{direct}_{mc} \times SF_{data/mc} \times \epsilon^{prompt}_{data} \times N_{γ+jet}$$
Quite good agreement (unfortunately...) between observed and Standard Model expected number of events

Set limits on mSUGRA/CMSSM and in Simplified Models
Systematic uncertainties considered on signal

- Parameter space dependent
  - Jet Energy Scale (~8%)
  - Jet Energy Resolution (~2%)
  - Theoretical uncertainties due to PDF (~6%)
  - Signal contamination (3-20%)

- Flat
  - Luminosity (2.2%)
  - Trigger inefficiency (2%)
  - Event cleaning (3%)
Limits from Jets+MH$_T$ On Simplified Models

CMS Preliminary
4.98 fb$^{-1}$, $\sqrt{s} = 7$ TeV
Jets+$H_T$

$\sigma^{\text{prod}} = 1/3 \times \sigma_{\text{NLO-QCD}}$

$\sigma^{\text{prod}} = \sigma_{\text{NLO-QCD}}$

$\sigma^{\text{prod}} = 3 \times \sigma_{\text{NLO-QCD}}$

95% CL Observed Limit [pb]
Razor Analysis

- The selection groups all final state objects (jets, leptons) into **two mega-jets**
- Calculate the **Razor variables** $R/M_R$ designed for this topology

$$M_R = \sqrt{(|\vec{p}_{j1}| + |\vec{p}_{j2}|)^2 - (p^2_{z1} + p^2_{z2})^2}$$

$$M_R^R = \sqrt{\frac{E_{T}^{miss}(p^2_{z1} + p^2_{z2}) - E_{T}^{miss} \cdot (p^2_{z1} + p^2_{z2})}{2}}$$

$$R = \frac{M_T^R}{M_R}$$

Peaks at $\sim M_\Delta = \frac{M_S^2 - M_{LSP}^2}{M_S}$

Edge at $\sim M_\Delta$

Ratio of two estimators of SUSY scale
It describes transverse shape of event

In simple case:
S = squark
X = jet

Example of SUSY
Razor Variables

\[ f(M_R) \propto e^{-S M_R} \]
\[ S = a + b(R_{cut})^2 \]

\[ f(R^2) \propto e^{-S R^2} \]
\[ S = c + d(M_R_{cut}) \]

Same functional phenomenology describes each SM background, EWK modelled by double exponential for each variable

\[ f(R^2, M_R) \propto \left[ k(M_R - M_R^0)(R^2 - R_0^2) - 1 \right] e^{-k(M_R - M_R^0)(R^2 - R_0^2)} \]
Razor Background Estimation

Final state BOX classification based on lepton ID

Minimum R2 and MR set by trigger requirements

Extended and unbinned maximum likelihood fit performed in 2D $R^2$-$M_R$ plane independently in each BOX

$$\mathcal{L}_b = \frac{e^{-(\sum_{j \in SM} N_j)}}{N!} \prod_{i=1}^{N} \left( \sum_{j \in SM} N_j P_j(M_{R,i}, R^2_i) \right)$$

Background functionally extrapolate to signal region, then toy MC generated accordingly with Likelihood function

Error bands represent statistical uncertainty only

Based on functional form shown in previous page
Razor CMSSM Limits

Model-independent representation of the results showing data-prediction / observation compatibility

Model-dependent interpretation, in CMSSM
CMS Preliminary  \( L_{\text{int}} = 4.98 \text{ fb}^{-1}, \sqrt{s} = 7 \text{ TeV} \)

\[ m_{1/2} \text{ [GeV]} \]

\[ m(\tilde{q}) = 1500 \]
\[ m(\tilde{g}) = 2000 \]
\[ m(\tilde{g}) = 2500 \]
\[ m(\tilde{q}) = 1000 \]
\[ m(\tilde{g}) = 1000 \]
\[ m(\tilde{g}) = 500 \]

\[ \tan(\beta) = 10 \]
\[ A_0 = 0 \text{ GeV} \]
\[ \mu > 0 \]
\[ m_t = 173.2 \text{ GeV} \]

R.Bellan

08 June 2012 – Susy.Had@CMS.cern.ch
Analysis motivated *General Gauge Mediation* (GGM) models, where gravitino (G) is the LSP, which get produced from other SUSY particle with *emission of a photon*. *NLSP is the neutralino*.

2 different scenarios investigated for the neutralino:

1. **Bino-like neutralino**: \( \chi_1^0 \)
   - (dominant decay in \( \gamma + G \))
   - \( \rightarrow \) di-\( \gamma \) analysis

2. **Wino-like neutralino/chargino**: \( \chi_1^\pm \)
   - (decay mostly in \( W + G \))
   - \( \rightarrow \) single photon analysis
The dominant background is **QCD**, which arises from jet energy resolution and tails. Selections: \( \geq 2 \) jets + photon and 1 jet + \( \geq 2 \) photons.

- **QCD background** estimated from non-isolated photon(s) sample and normalized/reweighted in a control region aside the search region.

- **Real MET background** (from EWK) estimated in \( ee, e\gamma, e \) control samples and reweighting for \( e \rightarrow \gamma \) probability (measured in data).
Best exclusion limits in Bino-like neutralino scenario from di-photon analysis, while single photon provides better exclusion in Wino-like neutralino scenario (see also backup)

Upper limit on signal production cross-section of order of 0.01 pb for bino-like $\chi^0$ scenario and 0.1 pb for wino-like $\chi^0$.

Experimental uncertainties on signal:

- Background prediction: 14 – 60%
- PDF on the acceptance: 1 – 15%
- Data / MC scale: 4%, Luminosity, 4.5%

Uncertainties on the signal cross section:

- Renormalization and factorization: 10-25%
- PDF on the cross-section: 5 – 70%
Summary

Results from searches for Super-Symmetry in fully hadronic ($M_{T}$+jets) and photon(s) + $M_{T}$ + jets final states have been presented

- Based on full 2011 data-set at 7 TeV collected by the CMS experiment

No-evidence of deviation from Standard Model predictions has been observed in any of the analyses nor channels

We proceed to set limits @ 95% C.L.

- in the reference cMSSM/mSUGRA $m_0$-$m_{1/2}$ plane (for parameters $A_0 = 0$, $\tan\beta = 10$, $\text{sign}(\mu) > 0$)

- on SUSY-like processes in a variety of Simplified Models

The exclusion power of the presented analyses (when applied to the same models) is comparable among each other and represent the current best CMS exclusion limits in these channels on the 7 TeV data.
A search for supersymmetry or similar new physics was carried out using a sqrt(s) = 7 TeV pp collisions data sample corresponding to 4.73/fb of integrated luminosity collected by the CMS experiment at the LHC. Fully hadronic final states were selected based on the cross-transverse mass variable MT2. Two complementary analyses were performed. The first targets the region of parameter space with medium to high squark and gluino masses, in which the signal can be separated from the Standard Model backgrounds by a strong cut on MT2. A second analysis has been optimized to look for events with a light gluino but heavy squarks. In this case, the MT2 cut was relaxed, but a higher jet multiplicity and at least one b-tagged jet were required. The dominant backgrounds in both analyses are different and they were estimated using data-driven methods. As no excess of events over the expected background was observed, exclusion limits were derived on the parameter space of the constrained minimal supersymmetric extension of the Standard Model (mSUGRA/CMSSM), as well as on a variety of Simplified Model Spectra.
MT2 Cuts

- At least one good primary vertex
- At least 3 jets with $p_T > 40$ GeV, $|\eta| < 2.4$ (≥ 4 jets for MT2b analysis)
- $H_T > 750$ GeV (driven by the trigger)
- $M_{T2}$ specific
  - $E_T > 30$ GeV to define a MET direction
  - $|\not{E}_T - \not{H}_T| < 70$ GeV to control upstream transverse momentum
- Event cleaning:
  - Veto events with jets failing PF-JID and with $p_T > 50$ GeV, $|\eta| < 2.4$
  - Standard noise filters
- Lepton veto: in order to reduce EWK and top backgrounds
- QCD removal: $\Delta \phi_{min}(\text{all jets}, E_T) < 0.3$ (only 4 leading jets used for MT2b)
- At least one $b$-jet identified by the SSVHPT b-tagger (for the MT2b analysis)
MT2 QCD Background

- QCD factorization method:

- Predict signal region (high $M_{T2}$, $\Delta \phi_{min} > 0.3$) from QCD enhanced region (high $M_{T2}$, $\Delta \phi_{min} < 0.2$)

- Exponential functional form motivated from simulation

$$r(M_{T2}) = \frac{N(\Delta \phi_{min} > 0.3)}{N(\Delta \phi_{min} < 0.2)} = e^{a-b \cdot M_{T2} + c}$$

- Fit region $50 < M_{T2} < 80$ GeV chosen to have minimal contamination from non-QCD data

- EWK background is subtracted from data, and a fit is performed to extract $a$ and $b$

- Constant term $c$ taken conservatively as the value of the fitted exponential at $M_{T2} = 250$ GeV

- Stability of method against fit variation is extensively checked in MC and data

The solid points correspond to raw data after all selection cuts, while the dashed points correspond to data after subtracting electroweak and $t\bar{t}$ backgrounds. An exponential fit (green curve) is performed in the region $50 < M_{T2} < 80$ GeV where the non-QCD contribution is minimal. The constant term of the final functional model (blue curve) is taken as the value of the exponential at $M_{T2} = 250$ GeV.
• Predict $Z \to \nu\bar{\nu}$ from $W \to \mu\mu$ after “removing” the muon and recomputing all relevant quantities.

• $W \to \mu\mu$ enriched sample obtained by using all selection cuts and:
  - One $\mu$ with $p_T > 10$ GeV
  - B-tag veto, using SSVHEM, to suppress $t\bar{t}$
  - $m_T(W) < 100$ GeV to reduce signal contamination

$Z \to \nu\bar{\nu}$ estimated as: $N_{Z\nu\nu} = N_{W\mu\mu} \cdot \frac{1}{\epsilon_{acc}\epsilon_{reco/iso}} \cdot R^{MC}$

• $\epsilon_{acc}$ muon acceptance from MC
• $\epsilon_{reco/iso}$ muon efficiencies obtained from Tag&Probe in data, parameterized in $p_T$, $\eta$ and $\Delta R(\mu, \text{closest jet})$
• $R^{MC}$ corrects for: kinematic differences, cross-sections, $M_T$ and b-tag veto efficiencies
• Backgrounds contributions are subtracted using MC, except $t\bar{t}$:
  - estimated using a $t\bar{t}$ enriched region in data by requesting 1 SSVHPT b-tag
MT2 Z → inv Background from W (II)

- Systematic uncertainties
  - uncertainties on b-tag scale factors
  - 100% uncertainties on MC subtracted backgrounds
  - Tag&Probe efficiency uncertainties
  - $R^{MC}$: pdf, MC statistics, and b-tag scale factors
  - Total uncertainties on final prediction ranges from 25% to $\sim$100%

![Graph showing MT2 analysis and CMS preliminary results](image)
MT2 Z \to \text{inv Background from } \gamma

- Select $\gamma$+jets events passing all selection cuts
  - $E_T < 100 \text{ GeV}$ to minimize signal contamination
  - $Z \to \nu \bar{\nu}$ mimicked by adding the recoed $\gamma$ to $E_T$
- $Z \to \nu \bar{\nu}$ estimated as: $R^{MC}(\frac{Z\nu\nu}{\gamma}) \cdot \text{Purity} \cdot N^\text{data}_\gamma$
- Perform extended ML fit in shower shape $\sigma_{\eta\eta}$ to extract prompt photon and background yields
- $R^{MC}$ accounts for residual kinematic differences, photon acceptance and reco efficiency
- Further x-checks are carried out to test the modeling of the $V$-boson $p_T$ spectra as well as $R^{MC}$
  - Comparing JetPhox NLO to MADGRAPH: good agreement found
  - Comparing $Z/\gamma$ ratio in data and MC using photon and $Z \to \ell\ell$ data
- Systematic uncertainties
  - MC statistics for $R^{MC}$
  - Additional 20\% on $R^{MC}$ for $M_{T2} < 275 \text{ GeV}$, 30\% for $M_{T2} > 275 \text{ GeV}$
    - Reflecting the precision to which we could validate the $p_T$ spectra and $Z/\gamma$ ratio
  - 5\% (bin dependent) purity uncertainty
  - Total uncertainties on final prediction ranges from 25\% to 65\%
MT2 Lost Lepton Background

- EWK and top background largely reduced by lepton veto. Remaining is:
  - electron or muon out of acceptance
  - electron or muon not isolated or not identified
  - hadronic $\tau$-decays

- Lost lepton contribution from W+jets and $t\bar{t}$ is estimated from electron and muon samples

$$N_{e,\mu}^{\text{lost lepton}} = (N_{e,\mu}^{\text{reco}} - N_{e,\mu}^{\text{bg}}) \frac{1 - \varepsilon_{e,\mu}}{\varepsilon_{e,\mu}}$$

- $\varepsilon_{e,\mu}$ accounts for acceptance and reco efficiency as well as difference in phase space

- $\Delta \phi_{\text{min}}(\text{jets}, E_T)$ cut dropped to increase statistics (was designed to fight QCD)

- $m_T < 100$ GeV required to reduce signal contamination in the lepton sample
  - Signal contamination can still be sizable and we thus taken it into account in the statistical interpretation

Systematic uncertainties
- 100% on MC subtracted backgrounds
- MC statistics
- additional 5% on $\varepsilon_{e,\mu}$ motivated from T&P data-MC differences
- Total uncertainty on final estimate ranges from 30% to 100%

MT2 Statistical Interpretation

- No significant excess observed in data, we proceed by setting upper limits
- MT2- and MT2b-analyses are not orthogonal, they are not statistically combined, rather the best limit is used for the final result
- The Higgs "CombinedLimit" tool is used for limit setting
- Statistical approach following most common CMS recommendations
- Likelihood constructed from Poisson probabilities for each bin in $M_{T2}$ and $H_T$

$$\mathcal{L} = \prod_{i=1}^{N_{\text{bins}}} \frac{\lambda_i^{n_i} e^{-\lambda_i}}{n_i!}, \quad \lambda_i = \mu \cdot s_i + \sum_{j=1}^{N_{\text{bkg}}} b_{ij}$$

- Test statistic $q_\mu$ constructed as the profile likelihood ratio: $q_\mu = -2 \ln \frac{\mathcal{L}(\text{data}|\mu, \hat{\mu})}{\mathcal{L}(\text{data}|\hat{\mu}, \hat{\theta})}$
- Toys tossed using frequentist approach
- We test the background-only and the signal+background hypotheses using a modified frequentist CLs approach

$$CL_{s+b} = P(q_\mu \geq q_{\mu}^{\text{obs}}|H_1), \quad CL_b = P(q_\mu \geq q_{\mu}^{\text{obs}}|H_0)$$

$$CL_s = \frac{CL_{s+b}}{CL_b}$$
MT2 data/MC comparison

MT2

HT > 750 GeV

MT2-b

HT > 750 GeV
A search for physics beyond the standard model is performed in events with at least three jets and large missing transverse momentum produced in 7 TeV proton-proton collisions. The data were collected with the CMS detector at the Large Hadron Collider, and correspond to an integrated luminosity of 4.98 fb$^{-1}$. No significant excess of events is observed above the expected backgrounds, which are determined from the data. The results are presented in the context of the constrained minimal supersymmetric extension of the standard model, and more generically for simplified models with new massive particles decaying to one or two jets and a stable weakly interacting particle.
Start with a $\gamma$+jets control sample: $p_T(\gamma)>100$ GeV combined isolation$<5.0$, pileup subtraction applied.

Subtract the contribution from secondary photons
- Purity is 98-99% as measured from data using isolation template technique

Subtract photons radiated from final state partons.
- JETPHOX: $(5\pm5)$% contribution

Correct for photon reconstruction & isolation efficiencies measured from data

Scale with $Z(\ell\ell)+$Jets/$\gamma+Jets$ production ratio taken from theory.

Systematic uncertainties
- theory uncertainty on ratio (21-42%)
- detector acceptance (5%)
- trigger (1-2%)
- mis-tag rate ($\sim1\%$)
- photon purity ($\sim2\%$)
- Data/MC efficiency s.f.
- fragmentation contribution (5%)

A search is performed for heavy particle pairs produced in $\sqrt{s} = 7$ TeV proton-proton collisions with 4.4 fb$^{-1}$ of data collected by the CMS experiment in 2011 at the CERN Large Hadron Collider. The search is sensitive to generic supersymmetry models provided superpartner particles are kinematically accessible, with minimal assumptions on properties of the lightest superpartner particle. The kinematic consistency of the selected events is tested against the hypothesis of heavy particle pair production using the dimensionless razor variable R, related to the missing transverse energy MET. The new physics signal is characterized by a broad peak in the distribution of MR, an event-by-event indicator of the heavy particle mass scale. This approach is complementary to MET based searches. After background modelling based on data and background rejection based on R and MR no significant excess of events is found beyond the Standard Model expectations. The results are interpreted in the context of the Constrained Minimal Supersymmetric Standard Model.
Each squark undergoes a two-body decay, meaning that, in the squark’s rest frame, the quark and LSP will each have the same characteristic momentum:

$$|\vec{P}_{jet}| = M_\Delta / 2 = \frac{M_\tilde{q}^2 - M_{\tilde{\chi}_1}^2}{2M_\tilde{q}}$$

This is the ‘scale’ of new physics processes we want to be sensitive to.
Two squarks decaying to quark and LSP. In their rest frames, they are two copies of the same monochromatic decay. In this frame $p(q)$ measures $M_\Delta$

$$M_\Delta/2 = \frac{M_\tilde{q}^2 - M_{\tilde{\chi}}^2}{2M_\tilde{q}}$$

In the rest frame of the two incoming partons, the two squarks recoil one against each other.

In the lab frame, the two squarks are boosted longitudinally. The LSPs escape detection and the quarks are detected as two jets.

If we could see the LSPs, we could boost back by $\beta_L$, $\beta_T$, and $\beta_{CM}$.

In this frame, we would then get $|p_{j1}| = |p_{j2}|$.

Too many missing degrees of freedom to do just this.
In reality, the best we can do is to compensate the missing degrees of freedom with assumptions on the boost direction.

- The parton boost is forced to be longitudinal.
- The squark boost in the CM frame is assumed to be transverse.

We can then determine the two by requiring that the two jets have the same momentum after the transformation.

The transformed momentum defines the $M_R$ variable:

$$M_R \equiv \sqrt{(E_{j1} + E_{j2})^2 - (p_{j1}^z + p_{j2}^z)^2}.$$
Razor Variables

- $M_R$ is boost invariant, even if defined from 3D momenta
- No information on the MET is used
- The peak of the $M_R$ distribution provides an estimate of $M_\Delta$
- $M_\Delta$ could be also estimated as the “edge” of $M_T^R$
- $M_T^R$ is defined using transverse quantities and it is MET-related
- The Razor (aka R) is defined as the ratio of the two variables

$$ R = \frac{M_T^R}{M_R} $$
Razor ID Shapes

The $M_R$ shape after a $R^2$ cut is exponential

$$f(M_R) \sim \exp^{-k_{M_R}M_R}$$

The exponent constant depends on the $R^2$ lower cut

$$k_{M_R} = a_{M_R} + b_{M_R}R^2_{\text{cut}}$$

The $R^2$ shape after a $M_R$ cut is exponential

$$f(R^2) \sim \exp^{-k_{R^2}R^2}$$

The exponent constant depends on the $M_R$ lower cut

$$k_{R^2} = a_{R^2} + b_{R^2}M_{\text{R cut}}$$

The two linear slopes are the same

$$b_{M_R} = b_{R^2}$$
The likelihood function is given by:

\[ \mathcal{L} = \frac{e^{-(\sum_{SM} N_{SM})}}{N!} \prod_{i=1}^{N} (\sum_{SM} N_{SM} P_{SM}(M_R, R^2)) \]

The background PDFs are given by:

\[ P_{SM}(M_R, R^2) = (1 - f_{2}^{SM}) \times F_{SM}^{1st}(R^2, M_R) + f_{2}^{SM} \times F_{SM}^{2nd}(R^2, M_R) \]

with:

\[ F(M_R, R^2) = \left[ b(M_R - M_R^0)(R^2 - R_0^2) - 1 \right] e^{b(M_R - M_R^0)(R^2 - R_0^2)} \]

To guide the fit, the likelihood is multiplied by Gaussian penalty terms which force the shape parameters around our a-priori knowledge (May 10 ReReco \( \sim 250 \) pb\(^{-1}\) b-tagged and b-vetoed samples)

This helps the fit to converge and have limited impact on the fit at minimum (errors dominated by the fit, not the a-priori knowledge)
Razor Background Prediction Strategy

- We fit a sample in its fit region. The fit is such that the likelihood refers to the full region already (i.e. it already extrapolate beyond the fit region).

- We generate a set of toy MCs. In each toy MC the background shape changes (generated according to the fit output and errors, including correlation).

- We obtain a distribution for the expected yield in a given signal-sensitive region, to be compared to observation.

- We evaluate agreement through a two-sides p-value.

- We use the same approach (adding signal in CLs calculation) to set a limit.

We have performed a search for supersymmetry in a gauge-mediation scenario with the gravitino as the lightest supersymmetric particle. The data sample corresponds to an integrated luminosity of 4.7 fb^-1 of pp collisions at sqrt(s) = 7 TeV, recorded by the CMS experiment at the LHC. We compare the missing transverse energy distribution in events containing either at least two photons plus at least one hadronic jet or at least one photon plus at least two hadronic jets to the spectra expected from standard model processes. No excess of events at high missing transverse energy is observed and upper limits on the signal production cross sections of order 0.01 pb (0.1 pb) at the 95% confidence level for the bino-like (wino-like) scenarios are determined for a range of squark, gluino, and neutralino masses.
Photon Analysis Signals

- **Fix Bino-like neutralino mass at 375 GeV**
  - Squark and gluino masses run from 400 to 2000 with 80 GeV binning

- **Fix Wino-like neutralino mass at 375 GeV**
  - Squark and gluino masses run from 400 to 2000 with 80 GeV binning

- **Fix squark mass at 2500 GeV**
  - Gluino mass from 400 to 2000 with 80 GeV binning
  - Neutralino mass from 150 to 1050 with 100 GeV binning
Photon Analysis Selection

- **Diphoton analysis selection**
  - $E_T(1) > 40$ GeV & $E_T(2) > 25$ GeV satisfying photon ID
  - $\Delta R(1,2) > 0.6$ for two photons
  - $\Delta \phi(1,2) > 0.05$
  - Reconfirm trigger requirement (IsoVL)

- **Single photon analysis selection**
  - $E_T > 80$ GeV satisfying photon ID
  - Reconfirm trigger requirement ($\text{CaloHT}>450$)
  - $N_{jets} \geq 2/3$
Di-Photon Background Estimation (I)

- **Real MET Background (called EW)**
  - $W\gamma (W\rightarrow e\nu)$ where an electron fakes a $\gamma$
  - Use data-driven method
  - Measure $e\rightarrow \gamma$ fake rate using $Z\rightarrow ee$
  - Apply fake rate to electron from $e\gamma$ selection

- **No real MET Background (called QCD)**
  - QCD: $\gamma\gamma$, $\gamma j$, $jj$ where jets fake photons
  - Use data-driven method
  - Select control samples where no real MET is expected
  - Take MET shape from the control samples and normalize the shape to candidate shape (MET < 20 GeV)

- **Fake-Fake (ff) Control Samples**
  - Fakes are defined as photons but inverting isolation and sigmaIetaIeta cut
  - Events with R9Id triggers are included to increase statistics

- **Electron-Electron (ee) Control Samples**
  - Select $Z\rightarrow ee$ samples with invariant mass between 81-101 GeV and subtracting sideband contributions
Electroweak Background

- Real MET
- Main contribution from $W\gamma$ ($W\rightarrow e\gamma$) where electron fakes photon
- Take MET distribution from $e\gamma$ sample
- Apply fake rate with the formula below

$$N_{\gamma\gamma}^{obs} = f_{e\rightarrow\gamma}N_{W\gamma}^{true}$$

$$N_{e\gamma}^{obs} = (1-f_{e\rightarrow\gamma})N_{W\gamma}^{true}$$

$$N_{\gamma\gamma}^{obs} = \frac{f_{e\rightarrow\gamma}}{1-f_{e\rightarrow\gamma}}N_{e\gamma}^{obs}$$

QCD background

- Fake MET
- Mostly QCD
- Two control samples
  - Select $Z\rightarrow ee$ sample by subtracting sideband to eliminate possible contributions from $t\bar{t}$ (called ee)
  - Select non-isolated photons (called ff)
- Take MET shape
  - JetPt reweighting is applied to the samples to simulate the hadronic recoils
  - Normalize the shape to $\gamma\gamma$ sample where MET < 20 GeV
Single Photon Background Estimation

**Main background $\gamma$/QCD:**
- Multi-jet: jet $\rightarrow$ $\gamma$, $\gamma$-jet

**MET (not intrinsic):**
- Dominated by hadronic activity: jet res, non-gaussian tails due to e.g dead cells
- Same effects for multi-jet & photon-jet

Define fake $\gamma$ selection to get data-driven c. s.:
- Disjunct to tight photon selection, but still photon-like
- The control-sample is re-weighted according to the photon-object pT:
  - Binned weights determined in control region MET<100 GeV
  - Jet-Multiplicity dependance: individual corrections for $\leq$2 jets & $\geq$3 jets, assign 10% systematic unc.
  - Stat. bin uncertainties propagated as systematics
  - Syst. unc. on extrapolation from low to high MET

**EWK already minor background**
- electron $\rightarrow$ $\gamma$

**Intrinsic MET from neutrinos:**
- W, ttbar

**Disjunct control sample:**
- Iso electron, reweighted according to $e \rightarrow \gamma$ fakerate

**Fake-rate:**
- measured pT-dependent on the Z-peak
- For photon pT>80 GeV: $0.006 \pm 0.0025$

**ISR/FSR minor background:**
- Initial- or final-state radiation of $\gamma$

**From MC simulation**
- Assign 100% systematic uncertainty on the cross-section

Simplified Models

In a simplified model a very reduced set of hypothetical particles is introduced; the phenomenological masses and the decay ratios are free parameters of the model. Such models allow us to describe and compare results of CMS analyses in a fashion independent from full/constrained models.

**Best exclusion limits for gluino and squark masses, for $m(\chi_0) = 0$ GeV (dark blue) and $m(mother)-m(\chi_0) = 200$ GeV (light blue)**
CMSSM Limits 1 fb\(^{-1}\) (Summary Plot)
In the process of precision determination of the luminosity collected by CMS in 2011, a slight time-dependent calibration drift was found in the calorimeter used as a luminometer.

To remedy this, we developed an independent luminosity determination using stable and precise pixel tracker.

Preliminary result presented at the LHC Luminosity Days suggests an upward change in the estimated luminosity for 2011 by ~6%, i.e. slightly outside the 1σ-band of our original estimate of the luminosity uncertainty.

- The corresponding change for the low-luminosity part of the run (2011A), which is the basis of our new and published precision measurements, is ~3.5%, well within the quoted systematics.

We are finalizing determination of the new luminosity measurement, with significantly better precision.

The anticipated change has a very minor effect on our preliminary results and no visible change in published limits.

Instability does not affect the 2010 luminosity determination, as it only affects high-luminosity running.
