### Ruggedness

### What is Ruggedness?

- For RF devices it is the ability to perform reliably when operated outside of "normal" conditions
- The more rugged a device is, the farther from normal conditions it operates without damage

### Measures of ruggedness

- VSWR A ratio that represents the impedance mismatch between device and load
- Energy Absorption (EA) measure of ability to absorb energy applied to the output terminal.<sup>(1).</sup>
- Maximum operating temperature

### Who needs it?

- Systems where normal operation is not into a matched load
  - Laser driver
  - Plasma generator
- Systems where availability is critical and unintended operation can cause a mismatch
  - Broadcast overdrive, causing Filter reflection, common because of DPD
  - Communications system antenna lcing
  - Broadcast system Damaged RF feed line
  - OOPS: tech forgot to shut down transmitter when operating changeover switch

Scenarios above describe impedance mismatch between the device and the load causing power to be reflected back to the device.

Mismatch also causes efficiencies to drop, resulting in sharply increased operating temperatures.

- two mechanisms:
  - 1. Lower efficiency generating power
  - 2. Reflected power is dissipated in device)

# Freescale's Latest Innovation 50V High Ruggedness Technology

- Developed primarily for high mismatch applications, such as Plasma generators, CO2 lasers, and MRI power amplifiers
- Key features:
  - 50V operation
  - Capable of handling >65:1 VSWR at all phase angle, >50V and 3 dB overdrive
  - High efficiency
  - Low thermal resistance

### **Unclamped inductive switch test**

Test procedure:

- 1. Individual test sockets or automated handlers can be used with the ITC55100B Testers.
- 2. The test controller generates a clean gate pulse waveform at the gate of the transistor
- 3. The energy dissipation capability of the DUT is stressed by increasing the load current and load voltage by attaching a unclamped inductor to the device's drain and source connections.

# **Freescale LDMOS Thermal performance**

- Freescale maintained industry leadership in LDMOS thermal performance
  - Achieved through continual improvements in die layout and packaging performance
- · Lower thermal resistances allows:
  - Lower die temperature
  - Longer device life by reducing impact of electro metal migration.

Confidential and Proprietary

### **Thermal Resistance**

- LDMOS device thermal resistance benefits from having a backside source that is thermally and electrically bonded to the package flange, which in turn is directly mounted to the heat sink.
- The low thermal resistance of LDMOS allows significantly higher CW power levels in a given package than with competing technologies

## **Thermal Resistance Measurement**

**Continuous Wave Test Signal** 

Thermal resistance on Freescale LDMOS are calculated using:

• 
$$R_{th} = (T_{die} - T_{case})/(P_{Dissipated})$$

- Infrared microscopy is used to measure die surface temperature (T<sub>die</sub>), during operation. During measurement, the die is exposed because this IR measurement method requires direct view of the die. The exposed die is coated to obtain a fixed emissivity value for IR thermal measurement. The hottest portion of the die is used as T<sub>die</sub>
- The case temperature  $(T_{case})$  is measured with a thermocouple that is mounted through the heatsink, so it comes in contact with the device flange underneath the hottest component within the package.
- Total power dissipated in the RF transistor is calculated by:
  - P<sub>dissipated</sub> = [RF input power + DC power(Idc\*Vdc)] [RF output power +RF reflected power]

# **Freescale LDMOS MTTF Calculator**

- MTTF (mean time to failure) is defined as a 10% reduction in current handling capability on 50% of the device within a given sample size. The primary factor in device failure is due to metal electro-migration on the die surface.
- By reducing device thermal resistance(R<sub>th</sub>) we can increase the active life time of Freescale LDMOS devices

# Freescale LDMOS MTTF

- Example: MRFE6VP6K1K25KH, operating at 1.25kW, with 74.6% efficiency at 230MHz.
- I<sub>Drain</sub> = 1250W/(74.6% x 50V) = 33.5A
- MRFE6VP61K25H have  $R_{th}$  of 0.15W/°C, Case temperature = 80°C
- Dissipated power =  $P_{DC} P_{out} + P_{in}$
- Dissipated power = 50V\*33.5A 1250W +6W = 431W
- $T_{rise} = 431W * 0.15W/^{\circ}C = 64.7 \ ^{\circ}C$
- $T_J = T_{rise} + T_{case} = 64.7 / C + 80 C = 144.7 C$

With  $R_{th}$  of 0.15W/°C, operating at 1.25kW 74.6% efficiency the MRFE6VP61K25H has a operating life time of **450 years.**
