

# Introduction to Transverse Beam Dynamics

Bernhard Holzer, CERN-LHC

The „ not so ideal world “

III.) Errors in Field and Gradient

## 19.) Chromaticity:

A Quadrupole Error for  $\Delta p/p \neq 0$

Influence of external fields on the beam: prop. to magn. field & prop. zu  $1/p$

dipole magnet  $\alpha = \frac{\int B dl}{p/e}$

$$x_D(s) = D(s) \frac{\Delta p}{p}$$

focusing lens  $k = \frac{g}{p/e}$

particle having ...  
to high energy  
to low energy  
ideal energy

**Chromaticity:  $Q'$**

$$k = \frac{g}{p/e} \quad p = p_0 + \Delta p$$

*in case of a momentum spread:*

$$k = \frac{eg}{p_0 + \Delta p} \approx \frac{e}{p_0} \left(1 - \frac{\Delta p}{p_0}\right) g = k_0 + \Delta k$$

$$\Delta k = -\frac{\Delta p}{p_0} k_0$$

*... which acts like a quadrupole error in the machine and leads to a tune spread:*

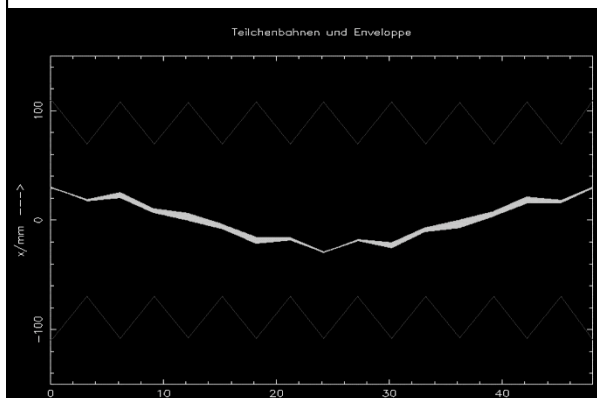

$$\Delta Q = -\frac{1}{4\pi} \frac{\Delta p}{p_0} k_0 \beta(s) ds$$

*definition of chromaticity:*

$$\Delta Q = Q' \frac{\Delta p}{p} ; \quad Q' = -\frac{1}{4\pi} \oint k(s) \beta(s) ds$$

***Where is the Problem ?***

## Tunes and Resonances

avoid resonance conditions:

$$m Q_x + n Q_y + l Q_s = \text{integer}$$

... for example:  $1 Q_x = 1$

... and now again about Chromaticity:

**Problem: chromaticity is generated by the lattice itself !!**

$Q'$  is a number indicating the size of the tune spot in the working diagram,

$Q'$  is always created if the beam is focussed

→ it is determined by the focusing strength  $k$  of all quadrupoles

$$Q' = -\frac{1}{4\pi} \oint k(s) \beta(s) ds$$

$k$  = quadrupole strength

$\beta$  = betafuncion indicates the beam size ... and even more the sensitivity of the beam to external fields

Example: LHC

$$\left. \begin{aligned} Q' &= 250 \\ \Delta p/p &= \pm 0.2 \cdot 10^{-3} \\ \Delta Q &= 0.256 \dots 0.36 \end{aligned} \right\}$$

→ Some particles get very close to resonances and are lost

in other words: the tune is not a point  
it is a pancake

*Tune signal for a nearly uncompensated chromaticity ( $Q' \approx 20$ )*

*Ideal situation: chromaticity well corrected, ( $Q' \approx 1$ )*

### *Tune and Resonances*

$$m \cdot Q_x + n \cdot Q_y + l \cdot Q_s = \text{integer}$$

*RA e Tune diagram up to 3rd order*

*... and up to 7th order*

*Homework for the operateurs:  
find a nice place for the tune  
where against all probability  
the beam will survive*

**Correction of Q':**

**Need: additional quadrupole strength for each momentum deviation  $\Delta p/p$**

1.) sort the particles according to their momentum  $x_D(s) = D(s) \frac{\Delta p}{p}$

... using the dispersion function

2.) apply a magnetic field that rises quadratically with x (sextupole field)

$$\left. \begin{aligned} B_x &= \tilde{g}xz \\ B_z &= \frac{1}{2} \tilde{g}(x^2 - z^2) \end{aligned} \right\} \frac{\partial B_x}{\partial z} = \frac{\partial B_z}{\partial x} = \tilde{g}x \quad \text{linear rising „gradient“:}$$

**Correction of Q':**

$k_1$  normalised quadrupole strength

$k_2$  normalised sextupole strength

**Sextupole Magnets:**

$$k_1(\text{sext}) = \frac{\tilde{g} x}{p/e} = k_2 * x$$

$$k_1(\text{sext}) = k_2 * D * \frac{\Delta p}{p}$$

**Combined effect of „natural chromaticity“ and Sextupole Magnets:**

$$Q' = -\frac{1}{4\pi} \left\{ \int k_1(s) \beta(s) ds + \int k_2 * D(s) \beta(s) ds \right\}$$

You only should not forget to correct Q' in both planes ...  
and take into account the contribution from quadrupoles of both polarities.

*corrected chromaticity*

*considering an arc built out of single cells:*

$$Q_x = -\frac{1}{4\pi} \left\{ \sum_{F\text{-quad}} k_{y'} \hat{\beta}_x l_{y'} - \sum_{D\text{-quad}} k_{y'd} \bar{\beta}_x l_{y'd} \right\} + \frac{1}{4\pi} \sum_{F\text{-sect}} k_2^F l_{sect} D_x^F \beta_x^F - \frac{1}{4\pi} \sum_{D\text{-sect}} k_2^D l_{sect} D_x^D \beta_x^D$$

$$Q_y = -\frac{1}{4\pi} \left\{ -\sum_{F\text{-quad}} k_{y'} \bar{\beta}_y l_{y'} + \sum_{D\text{-quad}} k_{y'd} \hat{\beta}_y l_{y'd} \right\} - \frac{1}{4\pi} \sum_{F\text{-sect}} k_2^F l_{sect} D_x^F \beta_x^F + \frac{1}{4\pi} \sum_{D\text{-sect}} k_2^D l_{sect} D_x^D \beta_x^D$$

## 20.) Insertions

## Insertions

... the most complicated one: the drift space

**Question to the audience: what will happen to the beam parameters  $\alpha$ ,  $\beta$ ,  $\gamma$  if we stop focusing for a while ...?**

$$\begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_s = \begin{pmatrix} C^2 & -2SC & S^2 \\ -CC' & SC' + S'C & -SS' \\ C'^2 & -2S'C' & S'^2 \end{pmatrix} * \begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_0$$

**transfer matrix for a drift:**

$$M = \begin{pmatrix} C & S \\ C' & S' \end{pmatrix} = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix} \longrightarrow \begin{matrix} \beta(s) = \beta_0 - 2\alpha_0 s + \gamma_0 s^2 \\ \alpha(s) = \alpha_0 - \gamma_0 s \\ \gamma(s) = \gamma_0 \end{matrix}$$

### **$\beta$ -Function in a Drift:**

let's assume we are at a symmetry point in the center of a drift.

$$\beta(s) = \beta_0 - 2\alpha_0 s + \gamma_0 s^2$$

as  $\alpha_0 = 0$ ,  $\rightarrow \gamma_0 = \frac{1 + \alpha_0^2}{\beta_0} = \frac{1}{\beta_0}$

and we get for the  $\beta$  function in the neighborhood of the symmetry point

$$\beta(s) = \beta_0 + \frac{s^2}{\beta_0} \quad !!!$$

**At the end of a long symmetric drift space the beta function reaches its maximum value in the complete lattice.  
-> here we get the largest beam dimension.**

-> keep  $l$  as small as possible

... clearly there is an

*But: ... unfortunately ... in general high energy detectors that are installed in that drift spaces are a little bit bigger than a few centimeters ...*

## 21.) Luminosity

*Example: Luminosity run at LHC*

$$\beta_{x,y} = 0.55 \text{ m} \quad f_0 = 11.245 \text{ kHz}$$

$$\varepsilon_{x,y} = 5 * 10^{-10} \text{ rad m} \quad n_b = 2808$$

$$\sigma_{x,y} = 17 \text{ } \mu\text{m}$$

$$I_p = 584 \text{ mA}$$

$$L = \frac{1}{4\pi e^2 f_0 n_b} * \frac{I_{p1} I_{p2}}{\sigma_x \sigma_y}$$

---

$$L = 1.0 * 10^{34} \text{ } 1/\text{cm}^2 \text{ s}$$

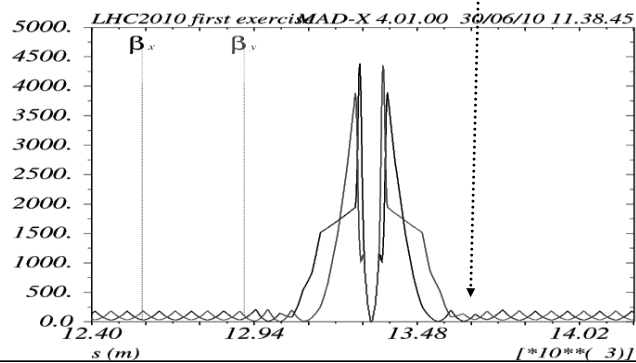

*Mini- $\beta$  Insertions: some guide lines*

- \* calculate the periodic solution in the arc
- \* introduce the drift space needed for the insertion device (detector ...)
- \* put a quadrupole doublet (triplet ?) as close as possible
- \* introduce additional quadrupole lenses to match the beam parameters to the values at the beginning of the arc structure

parameters to be optimised & matched to the periodic solution:  $\alpha_x, \beta_x, D_x, D'_x$   
 $\alpha_y, \beta_y, Q_x, Q_y$

8 individually powered quad magnets are needed to match the insertion (... at least)

*beam sizes in the order of my cat's hair !!*

## Mini- $\beta$ Insertions: Betafunctions

A mini- $\beta$  insertion is always a kind of special symmetric drift space.

→ greetings from Liouville

$$\alpha^* = 0$$

$$\gamma^* = \frac{1 + \alpha^2}{\beta} = \frac{1}{\beta^*}$$

$$\sigma^* = \sqrt{\frac{\epsilon}{\beta^*}}$$

$$\beta^* = \frac{\sigma^*}{\sigma'^*}$$

at a symmetry point  $\beta$  is just the ratio of beam dimension and beam divergence.

## The LHC Insertions

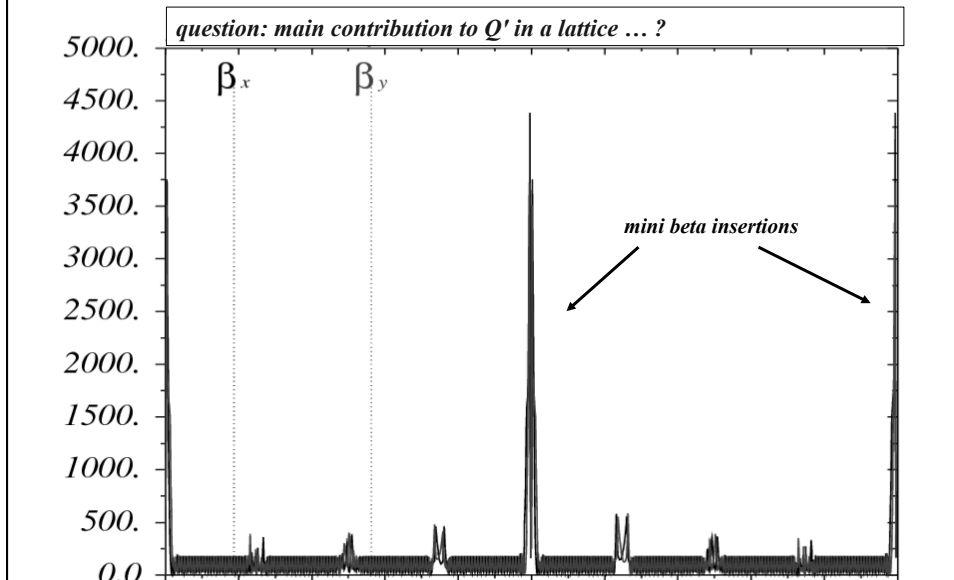

mini  $\beta$  optics

... and now back to the Chromaticity

$$Q' = -\frac{1}{4\pi} \oint k(s) \beta(s) ds$$

Clearly there is another problem ...

... if it were easy everybody could do it

Again: the phase space ellipse

for each turn write down - at a given

position „s” in the ring - the

single particle amplitude  $x$

and the angle  $x'$  ... and plot it.  $\begin{pmatrix} x \\ x' \end{pmatrix}_{s1} = M_{turn} * \begin{pmatrix} x \\ x' \end{pmatrix}_{s0}$

**A beam of 4 particles**

- each having a slightly different emittance:

## 25.) Particle Tracking Calculations

particle vector:  $\begin{pmatrix} x \\ x' \end{pmatrix}$

Idea: calculate the particle coordinates  $x, x'$  through the linear lattice ... using the matrix formalism.  
if you encounter a nonlinear element (e.g. sextupole): stop  
calculate explicitly the magnetic field at the particles coordinate

$$B = \begin{pmatrix} g'xz \\ \frac{1}{2}g'(x^2 - z^2) \end{pmatrix}$$

calculate kick on the particle

$$\Delta x'_1 = \frac{B_x l}{p/e} = \frac{1}{2} \frac{g'}{p/e} l (x_1^2 - z_1^2) = \frac{1}{2} m_{\text{sext}} l (x_1^2 - z_1^2) \quad \begin{pmatrix} x_1 \\ x'_1 \end{pmatrix} \rightarrow \begin{pmatrix} x_1 \\ x'_1 + \Delta x'_1 \end{pmatrix}$$

$$\Delta z'_1 = \frac{B_z l}{p/e} = \frac{g' x_1 z_1}{p/e} l = m_{\text{sext}} l x_1 z_1 \quad \begin{pmatrix} z_1 \\ z'_1 \end{pmatrix} \rightarrow \begin{pmatrix} z_1 \\ z'_1 + \Delta z'_1 \end{pmatrix}$$

and continue with the linear matrix transformations

## Installation of a weak ( !!! ) sextupole magnet

The good news: sextupole fields in accelerators cannot be treated analytically anymore.  
→ no equations; instead: Computer simulation  
„ particle tracking “

**Effect of a strong ( !!! ) Sextupole ...**

→ *Catastrophy !*

„dynamic aperture“

**Resume' :**

*quadrupole error: tune shift*  $\Delta Q \approx \int_{s_0}^{s_0+l} \frac{\Delta k(s) \beta(s)}{4\pi} ds \approx \frac{\Delta k(s) I_{quad} \bar{\beta}}{4\pi}$

*beta beat*  $\Delta \beta(s_0) = \frac{\beta_0}{2 \sin 2\pi Q} \int_{s_1}^{s_1+l} \beta(s_1) \Delta k \cos(2(\psi_{s_1} - \psi_{s_0}) - 2\pi Q) ds$

*chromaticity*  $\Delta Q = Q' \frac{\Delta p}{p}$

$$Q' = -\frac{1}{4\pi} \oint k(s) \beta(s) ds$$

*momentum compaction*  $\frac{\delta I_e}{L} = \alpha_p \frac{\Delta p}{p}$

$$\alpha_p \approx \frac{2\pi}{L} \langle D \rangle \approx \frac{\langle D \rangle}{R}$$

*beta function in a symmetric drift*  $\beta(s) = \beta_0 + \frac{s^2}{\beta_0}$

## Appendix I:

### Dispersion: Solution of the inhomogeneous equation of motion

$$\text{Ansatz: } D(s) = S(s) \int_{s_0}^{s1} \frac{1}{\rho} C(\tilde{s}) d\tilde{s} - C(s) \int_{s_0}^{s1} \frac{1}{\rho} S(\tilde{s}) d\tilde{s}$$

$$D'(s) = S' * \int \frac{1}{\rho} C dt + S \frac{1}{\rho} C - C' * \int \frac{1}{\rho} S dt - C \frac{1}{\rho} S$$

$$D'(s) = S' * \int \frac{C}{\rho} dt - C' * \int \frac{S}{\rho} dt$$

$$\begin{aligned} D''(s) &= S'' * \int \frac{C}{\rho} d\tilde{s} + S' \frac{C}{\rho} - C'' * \int \frac{S}{\rho} d\tilde{s} - C' \frac{S}{\rho} \\ &= S'' * \int \frac{C}{\rho} d\tilde{s} - C'' * \int \frac{S}{\rho} d\tilde{s} + \frac{1}{\rho} \underbrace{(CS' - S C')}_{= \det M = 1} \end{aligned}$$

remember: for  $C(s)$  and  $S(s)$  to be independent solutions the Wronski determinant has to meet the condition

$$W = \begin{vmatrix} C & S \\ C' & S' \end{vmatrix} \neq 0$$

and as it is independent of the variable „s“  $\frac{dW}{ds} = \frac{d}{ds} (CS' - SC') = CS'' - SC'' = -K(CS - SC) = 0$

we get for the initial conditions that we had chosen ...  $\left. \begin{matrix} C_0 = 1, & C'_0 = 0 \\ S_0 = 0, & S'_0 = 1 \end{matrix} \right\} W = \begin{vmatrix} C & S \\ C' & S' \end{vmatrix} = 1$

$$D'' = S'' * \int \frac{C}{\rho} d\tilde{s} - C'' * \int \frac{S}{\rho} d\tilde{s} + \frac{1}{\rho}$$

remember:  $S$  &  $C$  are solutions of the homog. equation of motion:

$$S'' + K * S = 0$$

$$C'' + K * C = 0$$

$$D'' = -K * S * \int \frac{C}{\rho} d\tilde{s} + K * C * \int \frac{S}{\rho} d\tilde{s} + \frac{1}{\rho}$$

$$D'' = -K * \left\{ S \int \frac{C}{\rho} d\tilde{s} + C \int \frac{S}{\rho} d\tilde{s} \right\} + \frac{1}{\rho}$$

$\underbrace{\hspace{10em}}_{=D(s)}$

$$D'' = -K * D + \frac{1}{\rho}$$

... or

$$\underline{\underline{D'' + K * D = \frac{1}{\rho}}}$$

qed

## Appendix II:

### Quadrupole Error and Beta Function

a change of quadrupole strength in a synchrotron leads to tune shift:

$$\Delta Q \approx \int_{s_0}^{s_0+l} \frac{\Delta k(s) \beta(s)}{4\pi} ds \approx \frac{\Delta k(s) * l_{quad} * \bar{\beta}}{4\pi}$$

tune spectrum ...

tune shift as a function of a gradient change

**But we should expect an error in the  $\beta$ -function as well ...  
... shouldn't we ???**

### Quadrupole Errors and Beta Function

a quadrupole error will not only influence the oscillation frequency ... „tune“  
... but also the amplitude ... „beta function“

split the ring into 2 parts, described by two matrices  
A and B

$$M_{turn} = B * A$$

$$A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

$$B = \begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix}$$

matrix of a quad error between A and B

$$M_{dist} = \begin{pmatrix} m_{11}^* & m_{12}^* \\ m_{21}^* & m_{22}^* \end{pmatrix} = B \begin{pmatrix} 1 & 0 \\ -\Delta kds & 1 \end{pmatrix} A$$

$$M_{dist} = B \begin{pmatrix} a_{11} & a_{12} \\ -\Delta kds a_{11} + a_{12} & -\Delta kds a_{12} + a_{22} \end{pmatrix}$$

$$M_{dist} = \begin{pmatrix} \sim & b_{11} a_{12} + b_{12} (-\Delta kds a_{12} + a_{22}) \\ \sim & \sim \end{pmatrix}$$

the beta function is usually obtained via the matrix element „m12“, which is in Twiss form for the undistorted case

$$m_{12} = \beta_0 \sin 2\pi Q$$

and including the error:

$$m_{12}^* = \underbrace{b_{11}a_{12} + b_{12}a_{22} - b_{12}a_{12}\Delta k ds}_{m_{12} = \beta_0 \sin 2\pi Q}$$

$$(1) \quad m_{12}^* = \beta_0 \sin 2\pi Q - a_{12}b_{12}\Delta k ds$$

As  $M^*$  is still a matrix for one complete turn we still can express the element  $m_{12}$  in twiss form:

$$(2) \quad m_{12}^* = (\beta_0 + d\beta) \sin 2\pi(Q + dQ)$$

Equalising (1) and (2) and assuming a small error

$$\beta_0 \sin 2\pi Q - a_{12}b_{12}\Delta k ds = (\beta_0 + d\beta) \sin 2\pi(Q + dQ)$$

$$\beta_0 \sin 2\pi Q - a_{12}b_{12}\Delta k ds = (\beta_0 + d\beta) \sin 2\pi Q \underbrace{\cos 2\pi dQ}_{\approx 1} + \cos 2\pi Q \underbrace{\sin 2\pi dQ}_{\approx 2\pi dQ}$$

~~$$\beta_0 \sin 2\pi Q - a_{12}b_{12}\Delta k ds = \beta_0 \sin 2\pi Q + \beta_0 2\pi dQ \cos 2\pi Q + d\beta_0 \sin 2\pi Q + d\beta_0 2\pi dQ \cos 2\pi Q$$~~

ignoring second order terms

$$-a_{12}b_{12}\Delta k ds = \beta_0 2\pi dQ \cos 2\pi Q + d\beta_0 \sin 2\pi Q$$

remember: tune shift  $dQ$  due to quadrupole error:  $dQ = \frac{\Delta k \beta_1 ds}{4\pi}$   
(index „1“ refers to location of the error)

$$-a_{12}b_{12}\Delta k ds = \frac{\beta_0 \Delta k \beta_1 ds}{2} \cos 2\pi Q + d\beta_0 \sin 2\pi Q$$

solve for  $d\beta$

$$d\beta_0 = \frac{-1}{2 \sin 2\pi Q} \{2a_{12}b_{12} + \beta_0 \beta_1 \cos 2\pi Q\} \Delta k ds$$

express the matrix elements  $a_{12}$ ,  $b_{12}$  in Twiss form

$$M = \begin{pmatrix} \sqrt{\frac{\beta_s}{\beta_0}} (\cos \psi_s + \alpha_0 \sin \psi_s) & \sqrt{\beta_s \beta_0} \sin \psi_s \\ \frac{(\alpha_0 - \alpha_s) \cos \psi_s - (1 + \alpha_0 \alpha_s) \sin \psi_s}{\sqrt{\beta_s \beta_0}} & \sqrt{\frac{\beta_0}{\beta_s}} (\cos \psi_s - \alpha_s \sin \psi_s) \end{pmatrix}$$

$$d\beta_0 = \frac{-1}{2 \sin 2\pi Q} \{2a_{12}b_{12} + \beta_0\beta_1 \cos 2\pi Q\} \Delta k ds$$

$$a_{12} = \sqrt{\beta_0\beta_1} \sin \Delta\psi_{0 \rightarrow 1}$$

$$b_{12} = \sqrt{\beta_1\beta_0} \sin(2\pi Q - \Delta\psi_{0 \rightarrow 1})$$

$$d\beta_0 = \frac{-\beta_0\beta_1}{2 \sin 2\pi Q} \{2 \sin \Delta\psi_{12} \sin(2\pi Q - \Delta\psi_{12}) + \cos 2\pi Q\} \Delta k ds$$

... after some TLC transformations ... =  $\cos(2\Delta\psi_{01} - 2\pi Q)$

$$\Delta\beta(s_0) = -\frac{\beta_0}{2 \sin 2\pi Q} \int_{s_1}^{s_1+l} \beta(s_1) \Delta k \cos(2(\psi_{s_1} - \psi_{s_0}) - 2\pi Q) ds$$

**Nota bene:** ! the beta beat is proportional to the strength of the error  $\Delta k$

!! and to the  $\beta$  function at the place of the error ,

!!! and to the  $\beta$  function at the observation point,  
(... remember orbit distortion !!!)

!!!! there is a resonance denominator
