## o LHC Physics Parameters 2011

Parameter	
Bunch spacing [ns]	50
Energy [TeV]	3.5
$\beta^*$ (IP1/IP2/IP5/IP8)	1.5/10/1.5/3 $\rightarrow$ 1/10/1/3
Bunch intensity	$1.5 \times 10^{11}$
Norm. emittance @ collision [ $\mu\text{m}$ ]	$\sim 2.5$
Total number bunches per ring	1380
Maximum injected batch [# bunches]	144
Minimum injected batch [# bunches]	12
Crossing angle (IP1,IP5) [ $\mu\text{rad}$ ]	120
Long. emittance @ injection [eVs]	0.38-0.53

## o Collimators

	2011	Tight (2012)
TCP IR7 [ $\sigma$ ]	5.7	4
TCSG IR7 [ $\sigma$ ]	8.5	6
TCLA IR7 [ $\sigma$ ]	17.7	8
TCT IR1/5 [ $\sigma$ ]	11.8	9.3
TCSG IR6 [ $\sigma$ ]	9.3	6.8
TCDQ IR6 [ $\sigma$ ]	9.8	7.3

**2011 parameters  
not  
extreme:**

**bunch spacing  
 $\beta^*$   
collimators**

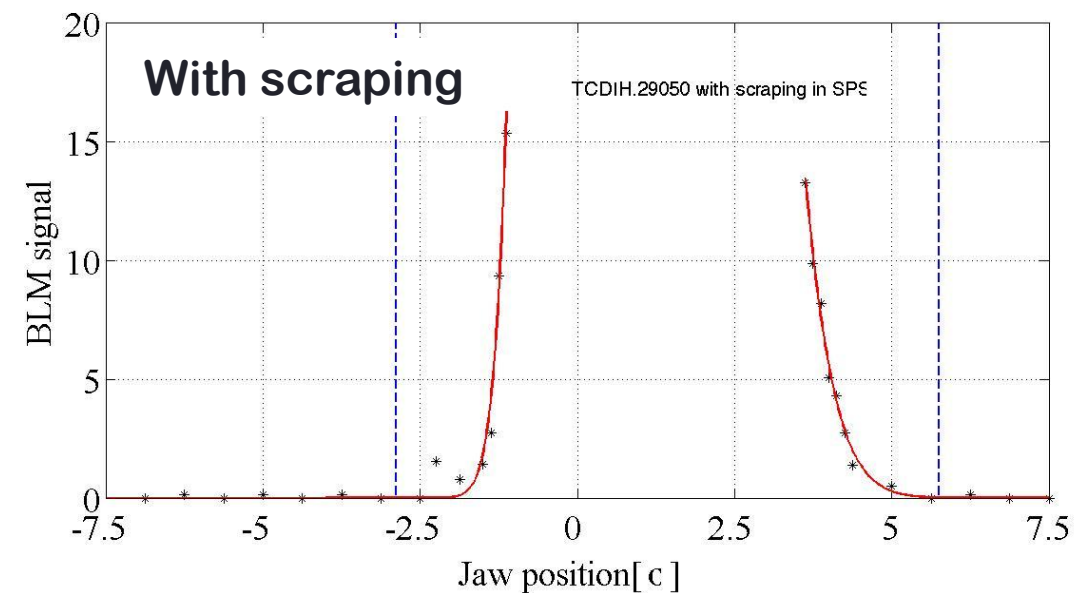

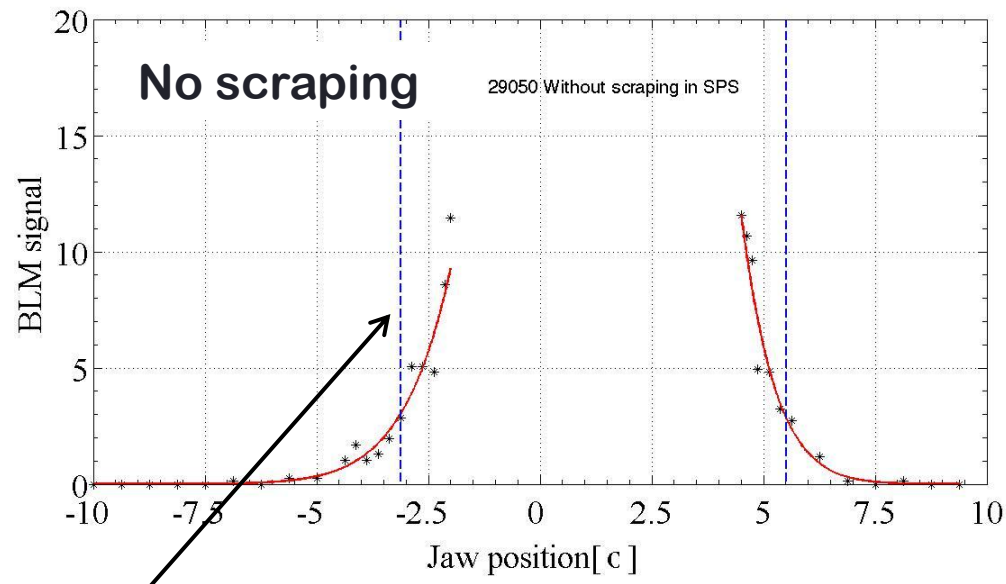

- o Remarkable 2011 performance:
  - 50 ns:  $1.5 \times 10^{11}$  p<sup>+</sup>/bunch, 1.9 μm norm. emittance at the exit of the SPS
  - 25 ns:  $0.98 \times 10^{11}$  , 2.5 μm

50 ns bunch spacing

- o Not all the intensity that is produced by the injectors can be used by the LHC
- o The long tails of the bunch distributions have to be scraped off to avoid high losses at the moment of injection into the LHC

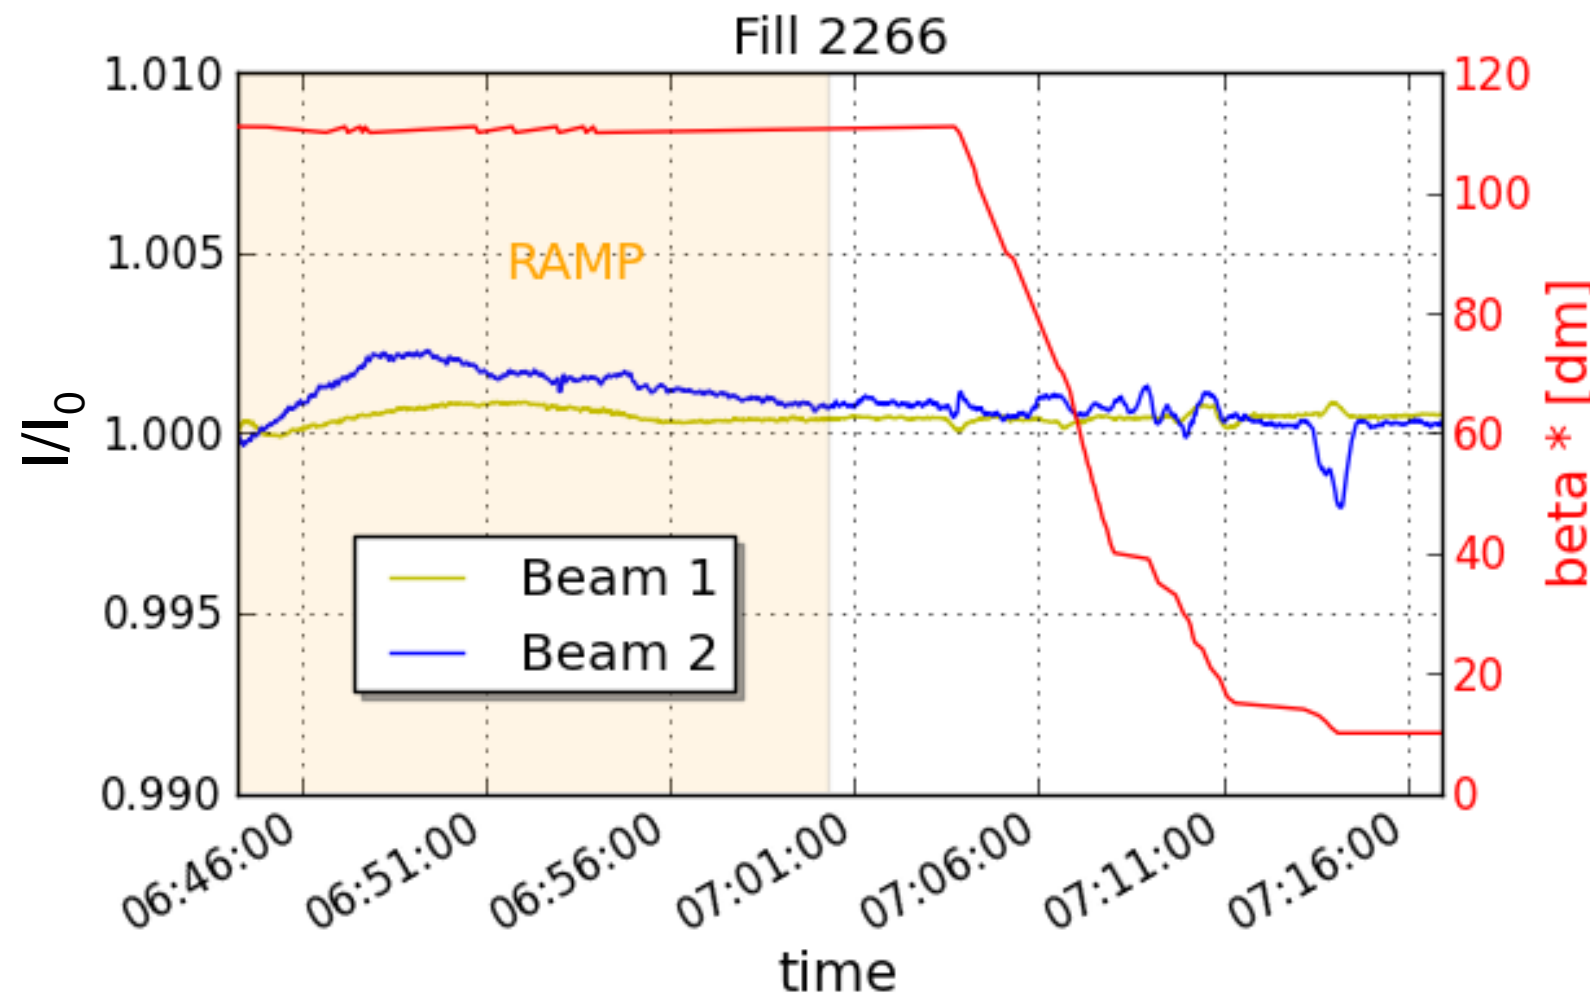

## Horizontal Transfer Line Collimator scan

Nominal setting of transfer line collimator

- o Injected nominal emittances ( $3.5 \mu\text{m}$ ) with scraping: no problem
- o Scrape **< 5 % of beam before extraction in the SPS**

- o **Excellent transmission: < 0.1 % loss**
- o Collimators close to beam at all times
- o Run through ramp and squeeze with
  - Orbit feedback
  - Tune feedback
  - Transverse feedback
- o LHC very reproducible – correct optics once !!

Note: FBCT measurement dependence on beam position and bunch length

- o Only started middle of 2011 to seriously investigate emittance preservation
- o Main limitation: instrumentation – no system fully adapted to measure physics beams through cycle
- o Several different profile measurement systems in the LHC
  - Wire scanners, low intensity only
  - Synchrotron Light Monitors (BSRT): continuous, bunch-by-bunch, not during energy ramp, calibration difficult
  - Beam-Gas Ionization Profile Monitor (BGI): continuous, not commissioned in 2011
  - (Luminosity)
- o Lessons learnt:
  - Importance of fast and well-calibrated continuous emittance measurement – emittance evolution needs to be available online: BSRT and BGI
  - Importance of using measured optics
- o Checked emittance preservation through different phases of cycle – presented results at Evian, Chamonix

# Significant Blow-up through Cycle

Analysed ~ 60 fills between mid July to mid August (50 ns,  $1.2 \times 10^{11}$ ,  $\beta^*=1.5$  m)

Comparison of **convoluted emittance from LHC luminosity** with **SPS wire scan** for 144 bunches:

On average ~ **20 - 30 %** growth between SPS flattop and collisions

1. No measureable blow-up from injection process
  - Sensitivity:  $\pm 10\%$
  
2. Blow-up during injection plateau  $\rightarrow$  bunch-by-bunch differences, smallest effect on total emittance blow-up
  - 0 – 10 %, different for different batches
  
3. Significant blow-up during the ramp
  - $> 20\%$  for  $1.6\ \mu\text{m}$
  
4. Blow-up during the squeeze for beam 1, horizontal plane
  - $> 20\%$
  
5. Absolute emittance growth independent of bunch intensity through cycle
  - $\Delta\varepsilon/\varepsilon \sim 0.5 - 0.6\ \mu\text{m}$  for convoluted, averaged emittance from luminosity

- Emittances are growing at injection – reasonably consistent with IBS although slightly faster

Simulations of IBS, uncoupled T. Mertens

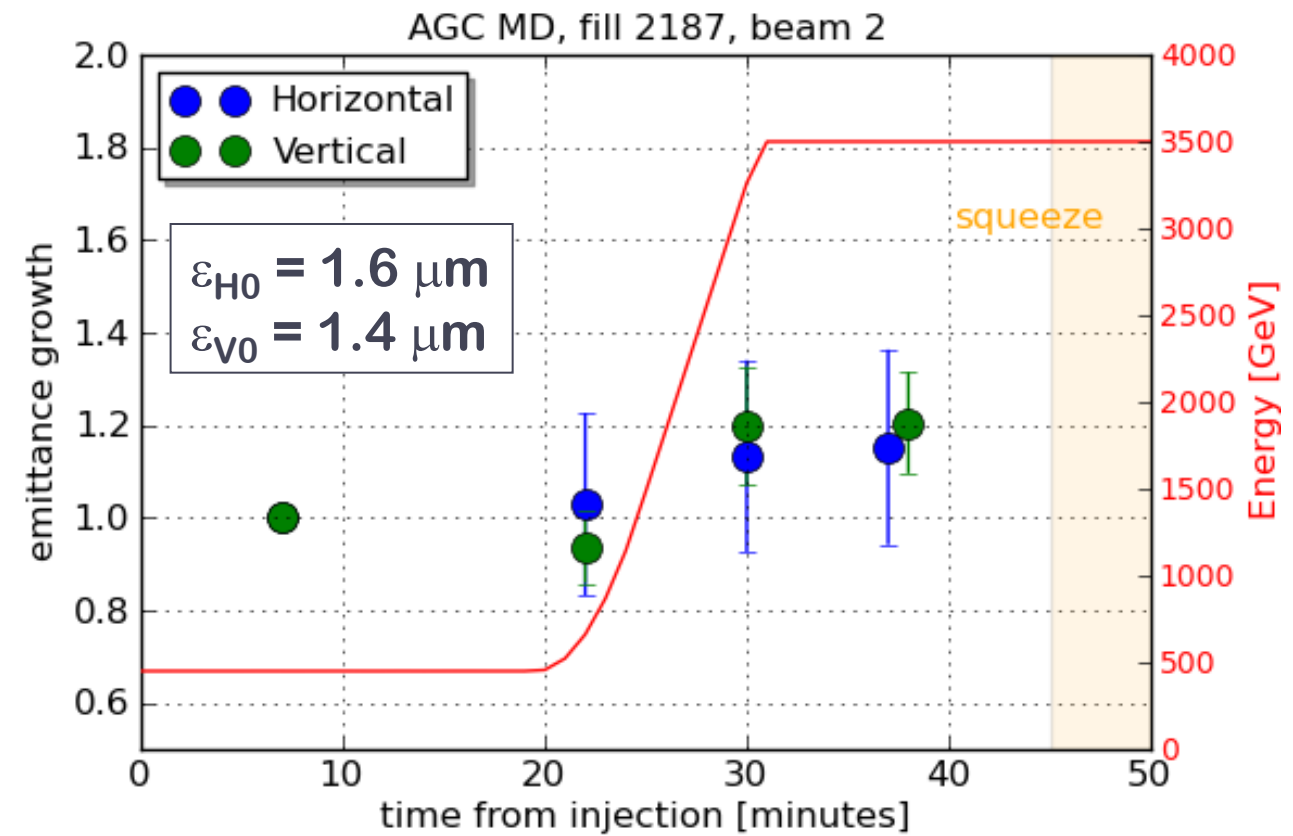

Horizontal emittance: ~ 10 % in 20 minutes

Filling about 30 minutes →  $\Delta\varepsilon/\varepsilon$  0 – 10% in H

More studies and IBS simulations to come in 2012

**Batch-by-batch longitudinal blow-up to possibly reduce effect**

Wire scans through the ramp, low intensity (3 12 bunch batches, 50 ns)

Used measured  $\beta$  at injection and flattop and linear interpolation between

**Blow-up during the ramp: measurement indicates  $> 20\%$  all planes**

Effect was reproduced in other test fills

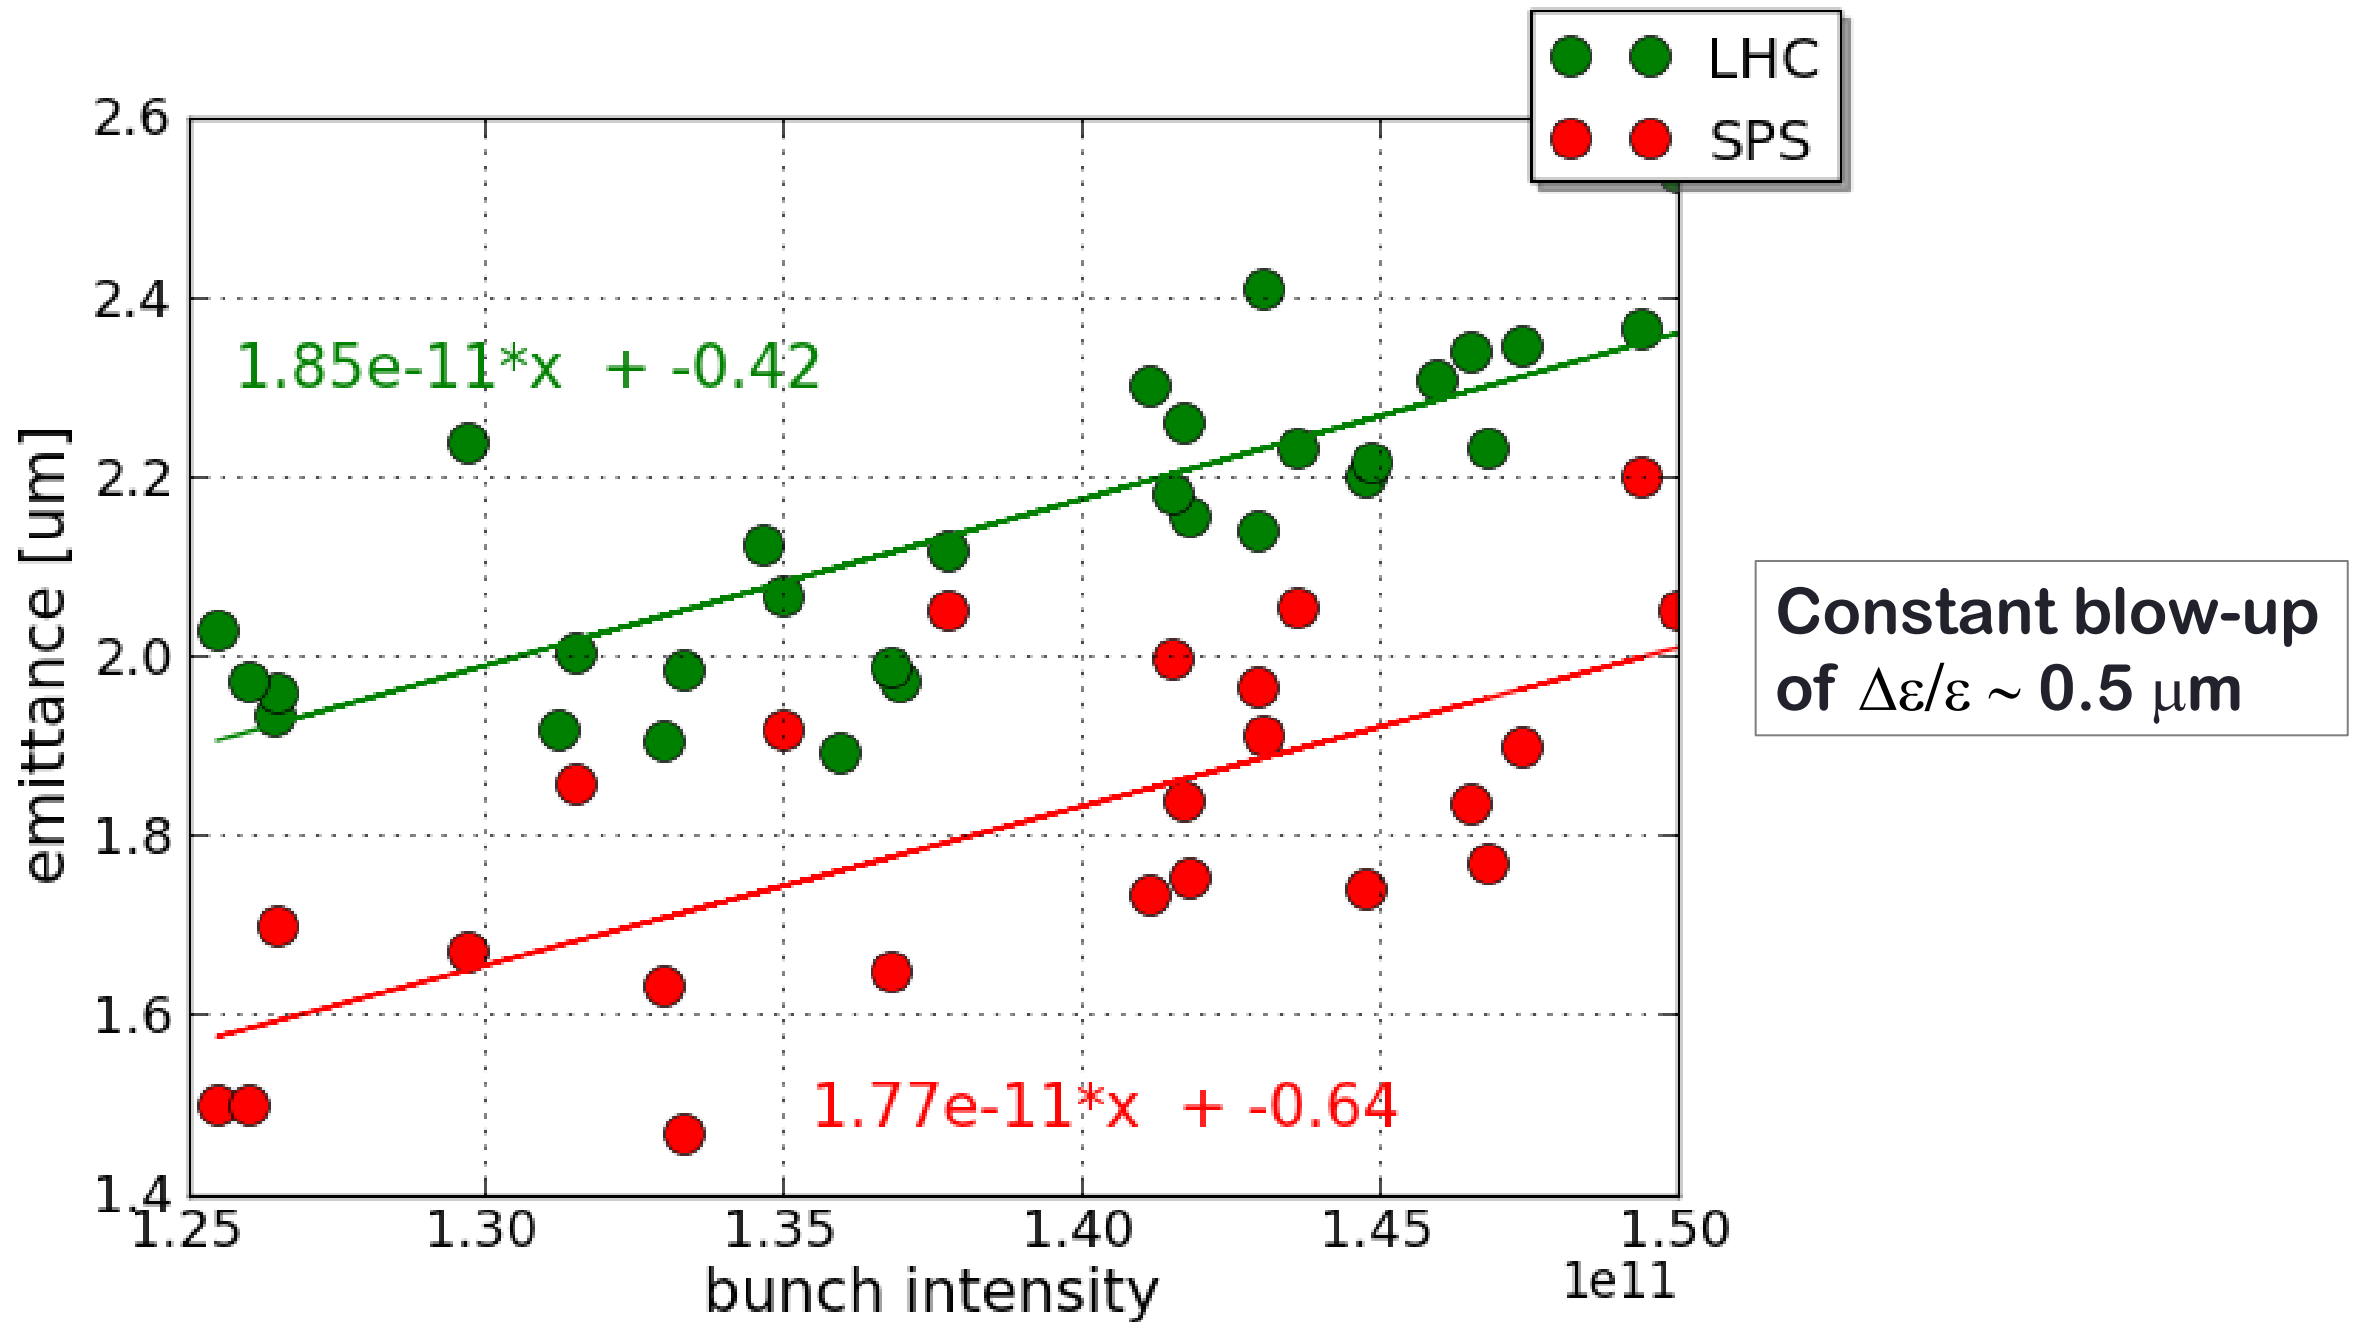

- o Evolution of the emittance through the squeeze for same fill as before

Measurements with BSRT

- o **Blow-up during squeeze for beam 1 H**

- Took measured beta at 3.5 m and 1 m from optics team into account
- Looked at BSRT from several physics fills, always blow-up of beam 1H
- Blow-up of beam 1 H between 5 and 1.5 m  $\beta^*$

Approximately constant absolute growth between SPS extraction and LHC collisions for different bunch intensities

- o Many, many improvements for instrumentation and MDs planned

2012 BSRT: online emittance evolution measurement

- o Injection plateau:
  - Batch-by-batch long. blow-up to be tested.
  - Shorten filling cycle
- o Ramp:
  - Source of blow-up not clear. Will test dependence on damper gain. Will be hardest to continuously observe. BGI needed.
- o Squeeze:
  - Only affected one beam and plane in 2011. Will check during commissioning with nominal intensity. Should be able to correct this in 2012
- o Goals: find sources of blow-up and/or dependence on  $\varepsilon$  and  $I_b$

- o Status after last scrubbing test, 24<sup>th</sup> of October 2011
  - Batches of 72 bunches, spaced by 1 us, circulating
  - E-cloud instability: emittances still far from being useful for physics

- o Fill 2186 – 25 ns physics fill 12 + 24 + 24 bunches
  - Injected emittances: 2.6  $\mu\text{m}$  convoluted
  - Into collision: 3.2  $\mu\text{m}$  – 0.6  $\mu\text{m}$  blow-up through cycle consistent with 50 ns observation
- o Transmission excellent – lifetimes never below 25 h.

# Future LHC Operation

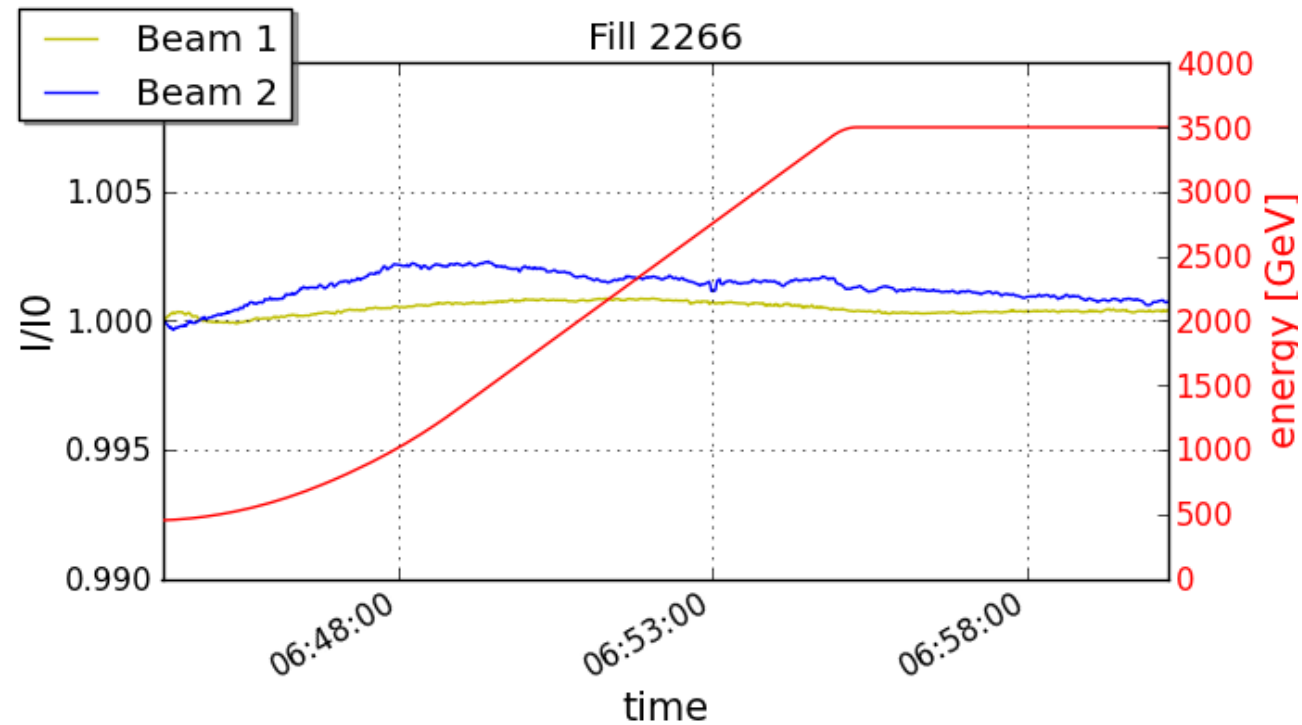

- o Difficult to say how representative 2011 operation is for nominal or HL LHC operation
  
- o Need 2012 for further experience
  - Smaller  $\beta^*$
  - Tight collimator settings and impedance
  - 25 ns and long-range beam-beam interaction

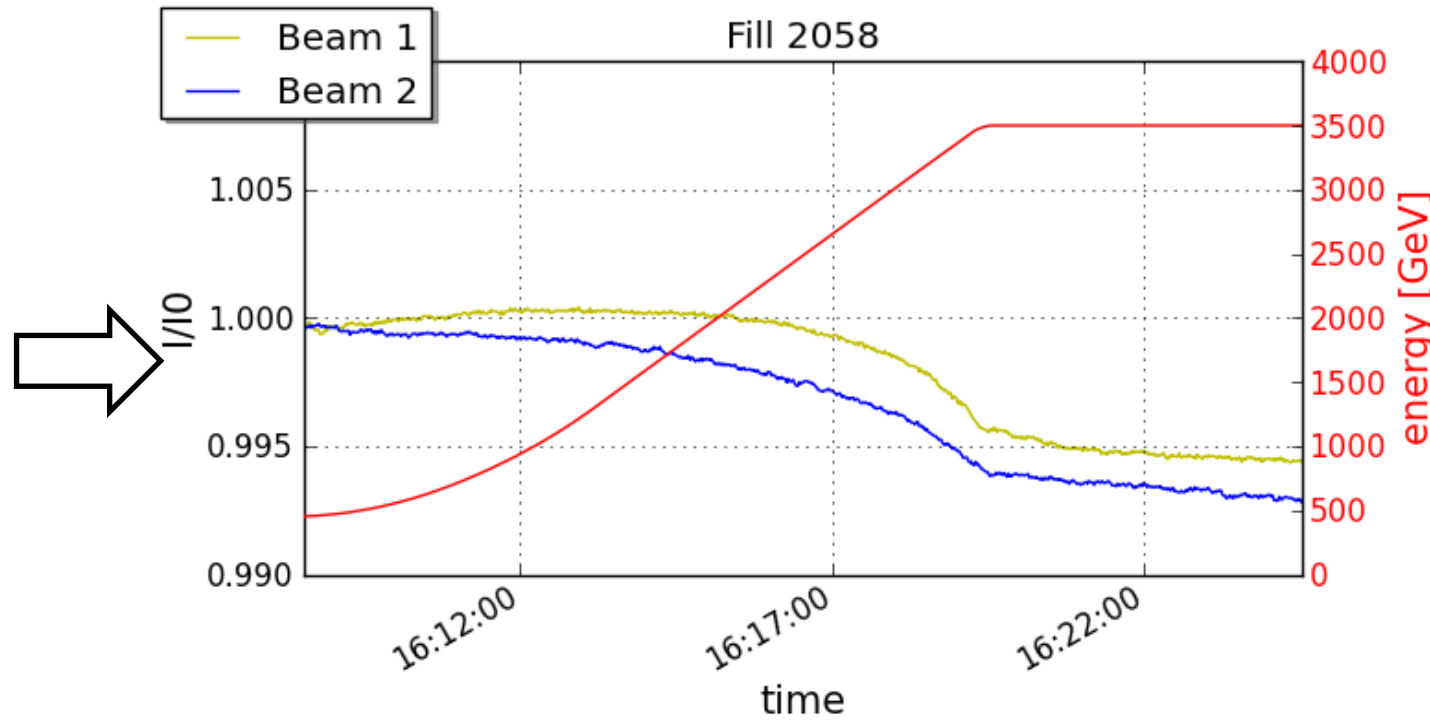

- o Transmission through the ramp degrades with tight collimator settings

Ramp loss < 0.1 %  
Standard collimator settings 2011

Ramp loss >0.5 %, Tight collimator settings 2011

- o Lost several % during squeeze due to orbit movements – scraping tails
  - Seems understood: leakage of crossing and separation bumps in the IRs.

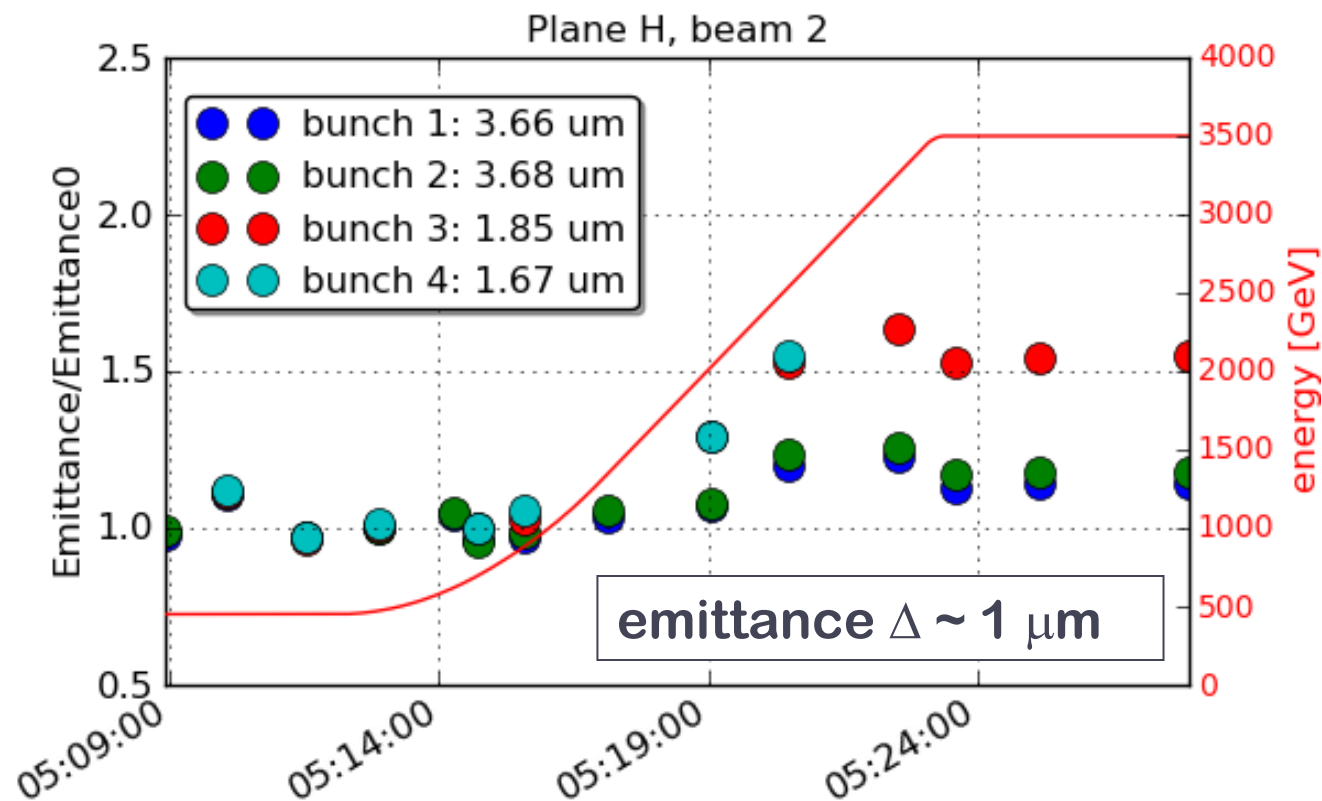

- o Transmission through the LHC cycle 2011 was excellent.
  - Loss < 0.1 %
  
- o Significant emittance blow-up through the LHC cycle
  - $\Delta\varepsilon/\varepsilon \sim 0.5 - 0.6 \mu\text{m}$  convoluted
  - Goal of 10 % blow-up through cycle is challenging
  
- o Need 2012 experience to get full(er) picture for transmission and emittance preservation
  - Smaller  $\beta^*$
  - Tight collimators
  - More powerful emittance diagnostics
  - MDs : emittance preservation, impedance, chromatic effects with smaller  $\beta^*$ , long-range,...

# EXTRA SLIDES

Last BI MD in 2011:

Ramp of 4 bunches per ring – different emittances

Unfortunately no useful wire scan data for beam 1

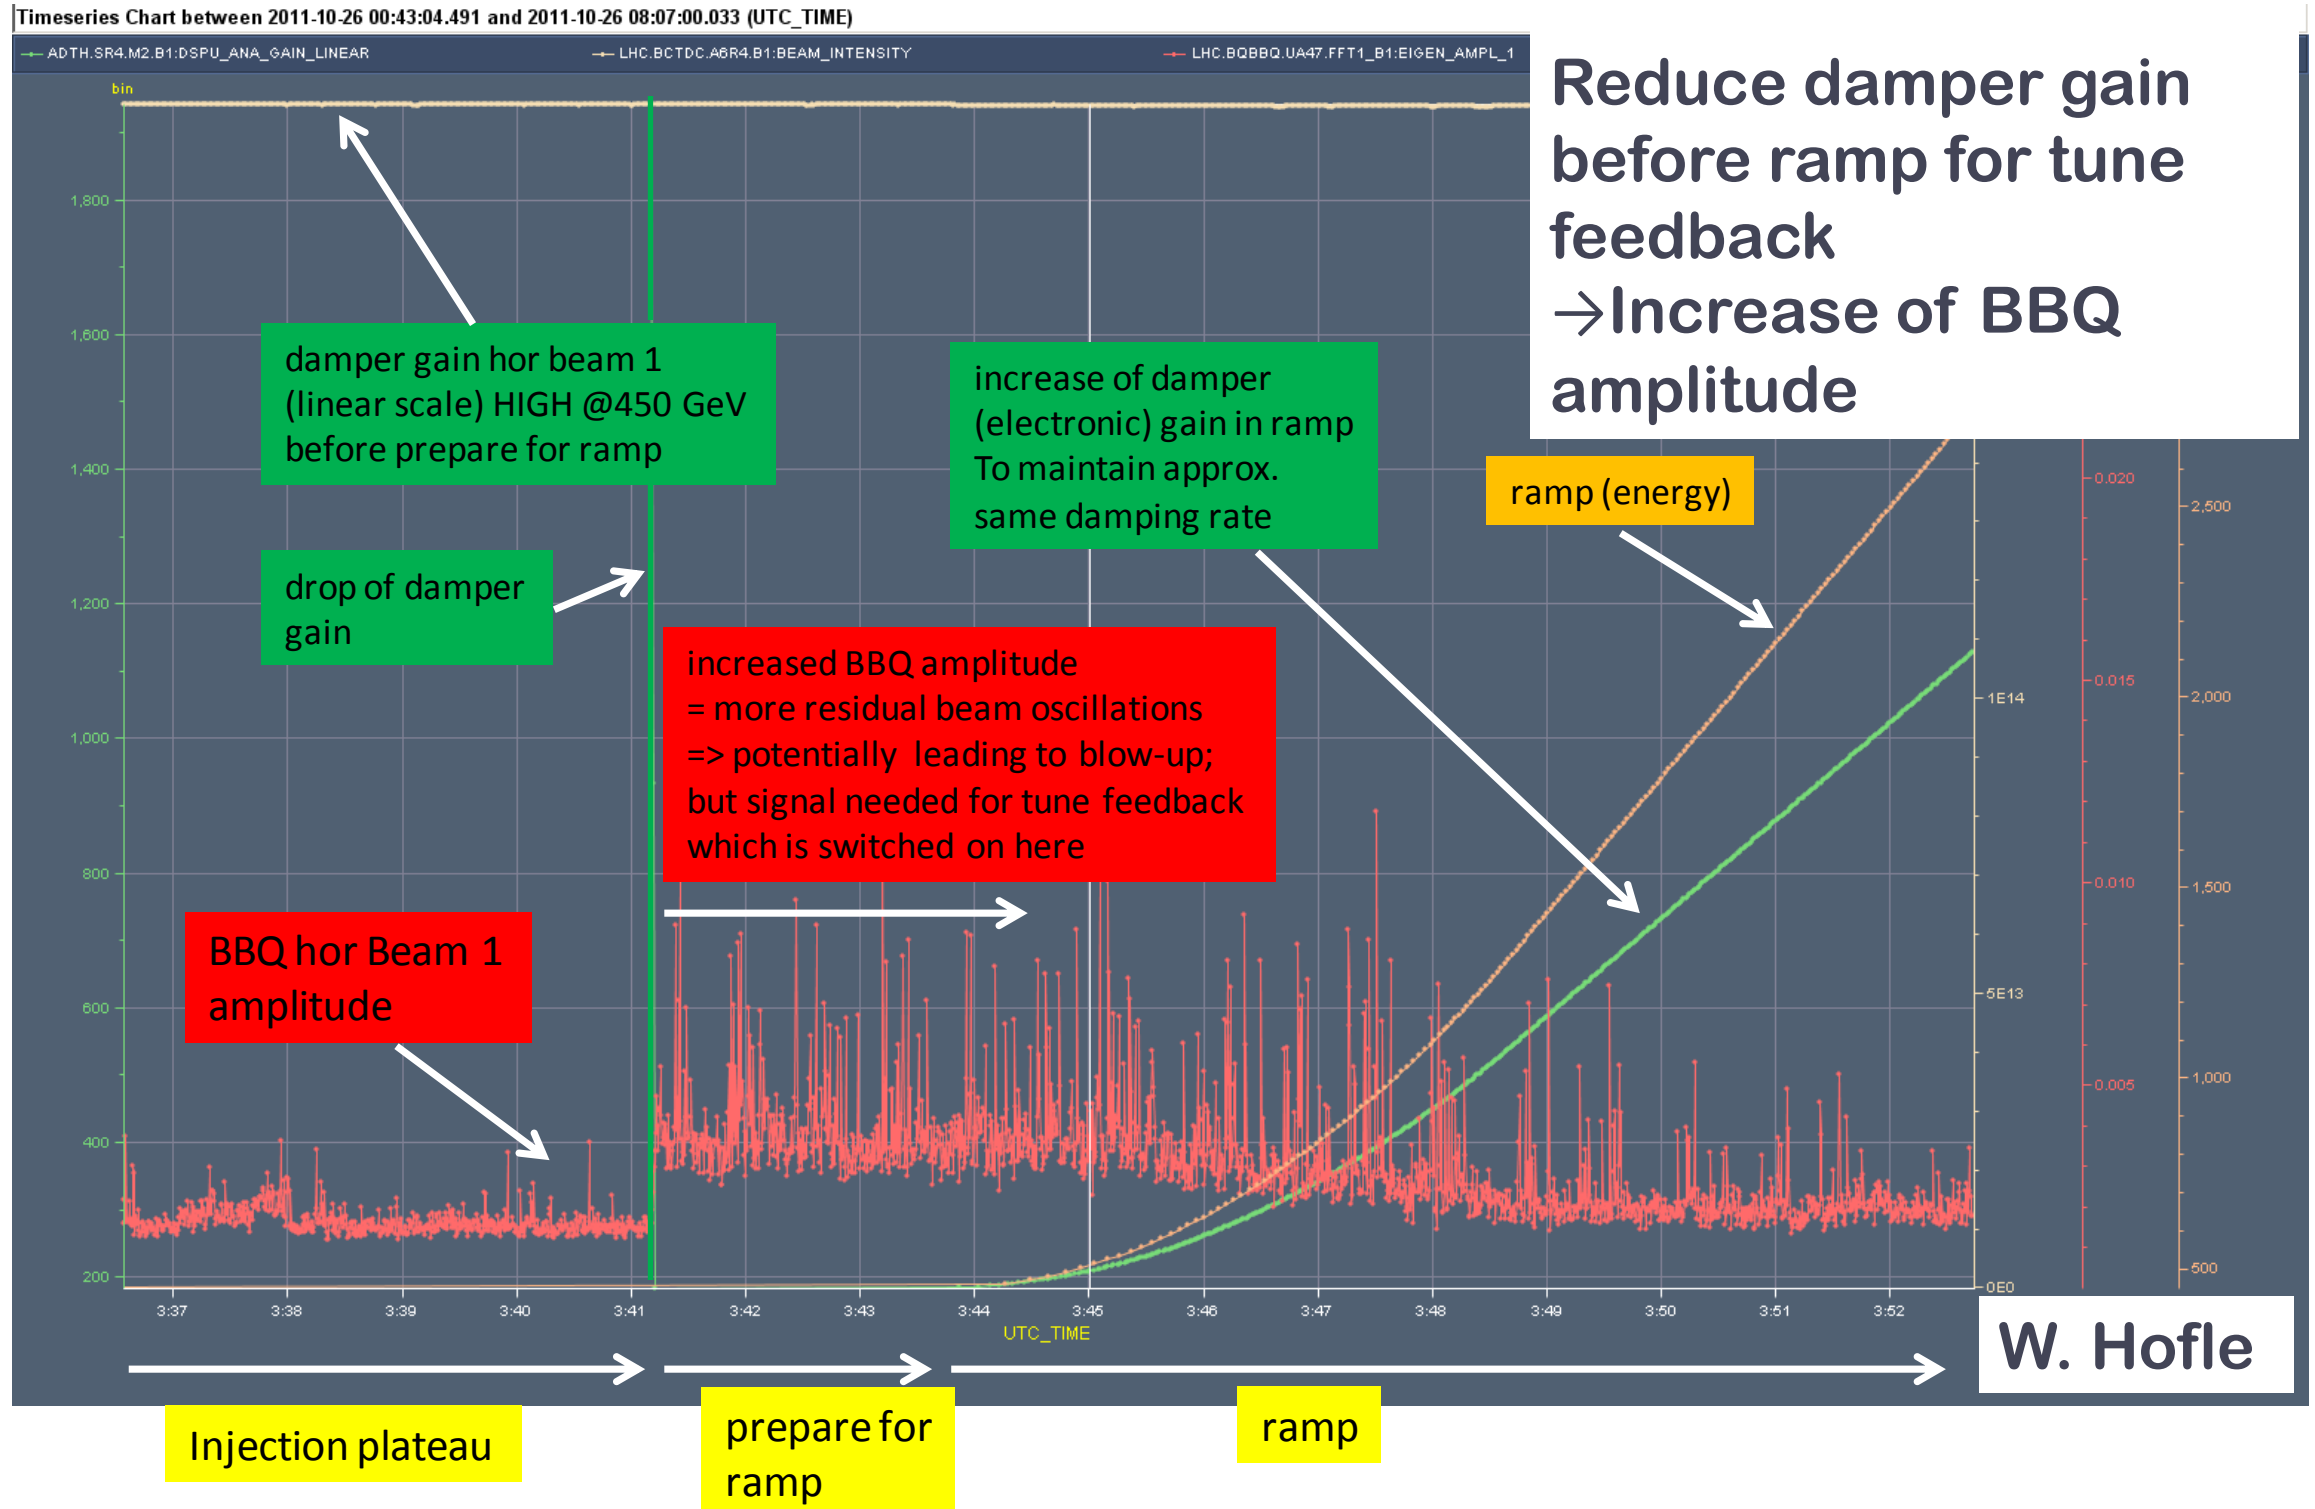

Relative growth different,  
but...different emittances grow by the same amount

Although larger than for 12 bunch trains

# Possible sources for growth @ ramp

- o Ramp still needs to be further optimized
  - Chromaticity,...
- o Effect of reduced damper gain during ramp?

## Fill 2182 Lumi per Crossing

- Lumi per bx
- Spec Lumi per bx
