

# Tetraquark-based analysis and predictions of the cross sections and distributions for the processes $e^+e^- \rightarrow \Upsilon(1S)(\pi^+\pi^-, K^+K^-, \eta\pi^0)$ near $\Upsilon(5S)$

Satoshi Mishima (INFN Rome)

Ahmed Ali, Christian Hambrock and S.M., Phys. Rev. Lett. 106, 092002 (2011)

## 1. What are tetraquarks?

- A tetraquark consists of a **colored diquark** and a **colored antidiquark**, which are strongly bounded by QCD forces.

cf. A hadronic molecule is a bound state of uncolored mesons, weakly bounded by pion exchanges.

- Two possible diquarks: Jaffe (05)

$|qq; \bar{3}_c(A) \bar{3}_f(A) 0_s^+(A)\rangle$  "good" diquark

$|qq; \bar{3}_c(A) 6_f(S) 1_s^+(S)\rangle$  "bad" diquark

- The light-scalar nonet fits the tetraquark picture. Maiani et al. (04)

- Some of exotic charmonium-like states, e.g., X(3872) and Y(4260), could be interpreted as tetraquarks. Maiani et al. (05)

## 2. $[bq][\bar{b}\bar{q}]$ tetraquarks Ali et al. (10)

- Mass spectra have been calculated with the constituent diquark Hamiltonian:

$$H = 2m_{[bq]} + H_{SS}^{(qq)} + H_{SS}^{(q\bar{q})} + H_{SL} + H_{LL}$$

- The diquark mass has been estimated by identifying  $Y_b(10890)$  as the lightest  $1^{--}$  state, or by scaling up the diquark mass determined from charmonium-like states, yielding  $m_{[bq]} \sim 5.3$  GeV.

- The  $1^{--}$  states can be produced in  $e^+e^-$  annihilations, in the range of the BaBar and Belle energies.

- There are **two almost degenerate states** with  $\Delta M \sim O(1)$  MeV. *mixture of  $Y_{[bu]}$  and  $Y_{[bd]}$*

## 3. Tetraquark interpretation of $Y_b(10890)$

- Belle observed anomalously huge cross sections for  $e^+e^- \rightarrow \Upsilon(5S) \rightarrow \Upsilon(nS)\pi^+\pi^-$  ( $n = 1, 2, 3$ ).

Process	$\Gamma_{e^+e^-}$	$\Gamma_{\Upsilon(1S)\pi^+\pi^-}$
$\Upsilon(2S) \rightarrow \Upsilon(1S)\pi^+\pi^-$	0.612 keV	0.0060 MeV
$\Upsilon(3S) \rightarrow \Upsilon(1S)\pi^+\pi^-$	0.443 keV	0.0009 MeV
$\Upsilon(4S) \rightarrow \Upsilon(1S)\pi^+\pi^-$	0.272 keV	0.0019 MeV
$\Upsilon(5S) \rightarrow \Upsilon(1S)\pi^+\pi^-$	0.31 keV	<b>0.59 MeV</b>

Chen et al. [Belle] (08)

**Larger by two-orders of magnitude!**

➡ There may exist exotic **tetraquark states  $Y_b(10890)$  near  $\Upsilon(5S)$ .**

- $\Upsilon(nS) \rightarrow \Upsilon(mS)\pi^+\pi^-$  is Zweig forbidden, while  $Y_b(10890) \rightarrow \Upsilon(mS)\pi^+\pi^-$  is **Zweig allowed**, which naturally explains huge cross sections. Ali, Hambrock, Aslam (10)

- Our estimate of the production rate is  $\Gamma(Y_b \rightarrow e^+e^-) \sim O(10)$  eV.

- The dominant decay modes of  $Y_b$  are  $Y_b \rightarrow B^{(*)}B^{(*)}$ , which are however hard to be observed due to large  $\sigma(e^+e^- \rightarrow \Upsilon(5S) \rightarrow B^{(*)}B^{(*)})$ .

## 4. Fit results and predictions

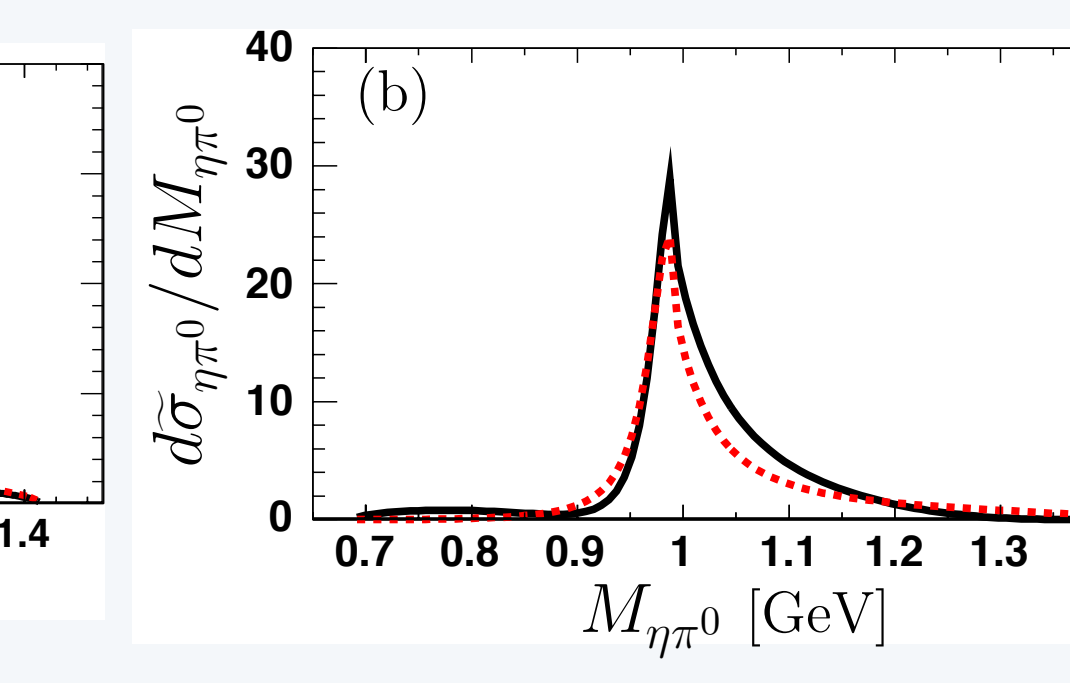

- We fit the  $\Upsilon(1S)\pi^+\pi^-$  data, taking into account resonant contributions in the dipion system with the Flatté model, in addition to nonresonant contribution.  $\chi^2/\text{d.o.f.} = 21.5/15$

➡ **Resonance dominance in the dipion invariant-mass spectrum.**

- Using the fitted parameters, we make predictions for  $e^+e^- \rightarrow Y_b \rightarrow \Upsilon(1S)K^+K^-$  and  $\Upsilon(1S)\eta\pi^0$ , which are dominated by  $f_0(980)+a_0(980)$  and  $a_0(980)$ , respectively.

$\sigma + f_0(980)$   $f_2(1270)$

Cross sections are normalized by the measured  $\sigma(\Upsilon(1S)\pi^+\pi^-)$ .
