

Precision Polarimetry for Future e^+e^- Linear Colliders

Jenny List (DESY)

on behalf of the Linear Collider Physics & Detector Study

ICHEP 2012, Melbourne

Introduction

Compton Polarimeters

Spin Tracking

At the e^+e^- Interaction Point

Conclusions

Two Linear Collider Concepts

CLIC

- ▶ $\sqrt{s} = 0.5, 1.4, 3$ TeV
- ▶ technology under development
- ▶ $P(e^-) = 80\%$,
 $P(e^+) = 0$ (x%)
- ▶ beam energy spread: 0.3%
- ▶ energy loss (Beamstrahlung): 28%

ILC

- ▶ $\sqrt{s} = 90, 200 \dots 500$ GeV (...1 TeV)
- ▶ technology proven (FLASH, ...)
- ▶ $P(e^-) \geq 80\%$,
 $P(e^+) \simeq 30\%$ (60%)
- ▶ beam energy spread: 0.1%
- ▶ energy loss (BS): 4.5%

Polarimetry Concept

Wanted:

- ▶ long-term luminosity weighted polarisation average

$$\langle P \rangle = \frac{\int P \cdot \mathcal{L} dt}{\int \mathcal{L} dt} \quad (1)$$

- ▶ for each data set, to per mille level precision!

Tool Kit:

- ▶ Compton polarimeters upstream (& downstream) of e^+e^- IP
- ▶ Spin tracking between polarimeters and IP
- ▶ Cross-check with e^+e^- collision data

Working Principle

Laser Compton scattering:

- ▶ $\mathcal{O}(10^3)$ events / bunch
- ▶ $\frac{d\sigma}{dE}$ depends on P_z
- ▶ $\frac{d^2\sigma}{dEd\phi}$ depends on $P_{x,y}$
- ▶ asymmetry w.r.t. to laser helicity $\sim P_z$ ($P_{x,y}$)

Magnetic Chicane:

- ▶ deflects scattered e^\pm away from beam
- ▶ transforms $E \rightarrow x \Rightarrow$ measure dN/dx
- ▶ 4 magnet design:
 - ▶ restores unscattered beam
 - ▶ renders position on detector independent of E_{beam}

Polarimeter Uncertainties & Detector Requirements

Polarimeter Uncertainties

- ▶ laser polarisation: $\leq 0.1\%$
- ▶ alignment w.r.t. beam: 0.1...0.2%
 - ▶ lateral position (“Compton edge”): need $\mathcal{O}(0.1 \text{ mm})$ for $\leq 0.1\%$
 - ▶ tilts: typ. 0.05%/mrad
- ▶ detector linearity: aim for 0.1...0.2%

⇒ detector design with excellent possibilities to monitor alignment and linearity mandatory!

Detector Requirements

- ▶ alignment & linearity
- ▶ excellent monitoring, if possible online
- ▶ homogeneous response
- ▶ robustness against backgrounds (beam gas, beam halo, e^+e^- pairs, muons, synchrotron rad.) esp. at downstream location
- ▶ dynamic range: factor $\mathcal{O}(10^2)$ near Compton edge

Gas Cherenkov Detector [JINST 7, P01019 (2012)]

- ▶ used in so far most precise Compton polarimeter (0.5..1% at SLD)
- ▶ robust against background via high Cherenkov threshold (10 MeV for e^- in C_4F_{10})
- ▶ in-situ monitoring improvements:
 - ▶ non-linearity to few per mille level \rightarrow use LED between trains
 - ▶ angular alignment based on multi-anode photon detectors
- ▶ testbeam operation of 2-channel prototype
 \rightarrow achieved tilt alignment of 0.1°

Alternative Detectors

Quartz Cherenkov Detector

[A. Vauth]

- ▶ high photon yield: $\sim 10^3$ photo e^- per Compton e^-
- ▶ can resolve Compton e^- peaks in photoelectron (QDC) spectrum
- ▶ \rightarrow “self-calibrating”
- ▶ optimised geometry based on Geant4 simulation

Silicon Pixel Detector

[G. Alexander, I. Ben Mordechai]

- ▶ option for transverse polarimetry
- ▶ standard LHC style pixel detector ok in terms of rad. hardness and occupancy (ILC upstream)
- ▶ simulation result based on ILC upstream chicane: can get $dP_y/P_y = 0.2\%$

Alternative Detectors

Quartz Cherenkov Detector

[A. Vauth]

- ▶ high photon yield: $\sim 10^3$ photo e^- per Compton e^-
- ▶ can resolve Compton e^- peaks in photoelectron (QDC) spectrum
- ▶ \rightarrow "self-calibrating"
- ▶ optimised geometry based on Geant4 simulation

Silicon Pixel Detector

[G. Alexander, I. Ben Mordechai]

- ▶ option for transverse polarimetry
- ▶ standard LHC style pixel detector ok in terms of rad. hardness and occupancy (ILC upstream)
- ▶ simulation result based on ILC upstream chicane: can get $dP_y/P_y = 0.2\%$

Spin Tracking in Beam Delivery System

[M. Beckmann]

From upstream via IP to downstream

- ▶ using BMAD, based on full T-BMT equation
 - ▶ for B_{\perp} only: $\theta_{spin} = \left(\frac{g-2}{2} \cdot \gamma + 1\right) \cdot \theta_{orbit} \simeq 568 \cdot \theta_{orbit}$
 - ▶ start with $P_z = 80\%$, show median $\pm 1\sigma$ band from 1000 runs
-
- ▶ perfect lattice
 - ▶ 5(10) μm random misalignments (& corr. kickers, fast-feedback)
 - ▶ + detector solenoid, anti-DID, crab cavities
 - ▶ + collisions (500 GeV, w.s.)

Measuring the Depolarisation

- ▶ collision effect at IP $\simeq 0.2\%$
- ▶ upstream measurement very close to $\langle P \rangle$
- ▶ P_z drops another $1.2\% \pm 0.5\%$ from IP to downstream pol.
- ▶ dominated by energy spread after collision and extraction line quad's
- ▶ correlation with y position:
- ▶ reduce effect by small laser spot?

⇒ complement polarimeters with longterm $\langle P \rangle$ from collision data

Measuring the Depolarisation

- ▶ collision effect at IP $\simeq 0.2\%$
- ▶ upstream measurement very close to $\langle P \rangle$

- ▶ dominated by energy spread after collision and extraction line quad's
- ▶ correlation with y position:
- ▶ reduce effect by small laser spot?

⇒ complement polarimeters with longterm $\langle P \rangle$ from collision data

Depolarisation at CLIC [J. Esberg, D. Schulte et al]

- ▶ higher energy, smaller bunches \Rightarrow need strong field effects (c.f. talk by A. Hartin)!
- ▶ implemented in GuineaPig++
- ▶ studied depolarisation in collision as function of vertical offset of the beams ($\sigma_y = 1$ nm)
- ▶ total depolarisation: $\gtrsim 6\%$
- ▶ only in 1% of nominal \sqrt{s} : $\lesssim 0.1\%$
- ▶ a priori don't know actual $\sqrt{s'}$ on single event basis, e.g. for channels with missing 4-momentum

$\langle P \rangle$ from leptonic single W / Z and single γ [G. Wilson]

- ▶ dominated by $e^+e^- \rightarrow W^\pm e^\mp \nu_e$ and $e^+e^- \rightarrow \nu_e \bar{\nu}_e Z / \gamma$
- ▶ measure total 4 cross-sections for up to 9 possible polarisation configurations: $+-, -+, ++, --, -0, +0, 0-, 0+, 00$
- ▶ determine either $|P_{e^-}^L| = |P_{e^-}^R|$ and $|P_{e^+}^L| = |P_{e^+}^R|$ or additionally low small differences δ_- and δ_+
- ▶ assume 2 ab^{-1} at 3 TeV, 25% $+-$, 25% $-+$, 50% others
- ▶ δ 's free:
 $\Delta|P_{e^+}^L|/|P_{e^+}^L| = 0.3\%$, $\Delta|P_{e^-}^L|/|P_{e^-}^L| = 0.16\%$, $\delta = 0 \pm 0.27\%$

stat. sign. (500 fb^{-1} per hel. config.)

Luminosity weighted polarisation average

$\langle P \rangle$ from $d\sigma(e^+e^- \rightarrow W^+W^-)/d\cos\theta$ [I. Marchesini]

- ▶ measure for 4 sign combinations $P = (+, -), P = (-, +), P = (+, +), P = (-, -)$
- ▶ fit for $|P(e^+)|, |P(e^-)|$ (and triple gauge couplings)
- ▶ optionally unequal $|P| \Rightarrow$ take differences from polarimeters
- ▶ can determine polarisations to 0.1...0.2% level with $\mathcal{O}(1\text{ab}^{-1})$
- ▶ systematically limited by polarimeters \Rightarrow minimize difference by fast helicity reversal or need additional runs with one $P = 0$

60% e^+ 30% e^+ 

Conclusions

- ▶ per mille level determination of the luminosity weighted polarisation average $\langle P \rangle$ needs
 - ▶ excellent Compton polarimetry
 - ▶ detailed understanding of spin transport between polarimeter(s) and IP
 - ▶ detailed understanding of collision effects
 - ▶ cross-check from collision data
- ▶ in all these aspects progress has been achieved
- ▶ measuring $\langle P \rangle$ to a few per mille seems achievable for ILC
- ▶ less studied so far, but probably also valid for CLIC
