CERN-SPSC-2011-020 / SPSC-I-240

# Outline

- Motivation: Protons as Driver for HEP  
(High Energy Physics)
- The Planned Experiment
- High Energy Outlook

# LWFA and HEP – Staging Unavoidable

Example Linear Collider  
(15 MW beam power, 3 TeV):

- Energy Laser pulse:  
0.5 J – 40 J
- Energy need witness bunch:  
300 J – 1000 J
- This means many stages  
at kHz rep rates!
- Alignment / Synchronization  
very challenging ( $\ll \lambda_p$ ) !

Picture:  
Leemans 2009, doi: 10.1063/1.3099645

# PWFA - Transformer Ratio and e<sup>-</sup>-Driver

- For unshaped bunches, the energy gain of the witness bunch is limited by the Transformer Ratio\*:

$$\Delta E_{witness} = R \cdot E_{drive} \quad R = 2 - \frac{N_{witness}}{N_{drive}}$$

- This means means that to reach the TeV scale, we need a high energy drive beam or again several stages.
- For a high energy electron drive beam, Synchrotrons get prohibitively expensive due to Synchrotron radiation losses ( $\propto \frac{E^2}{m^4}$ ).

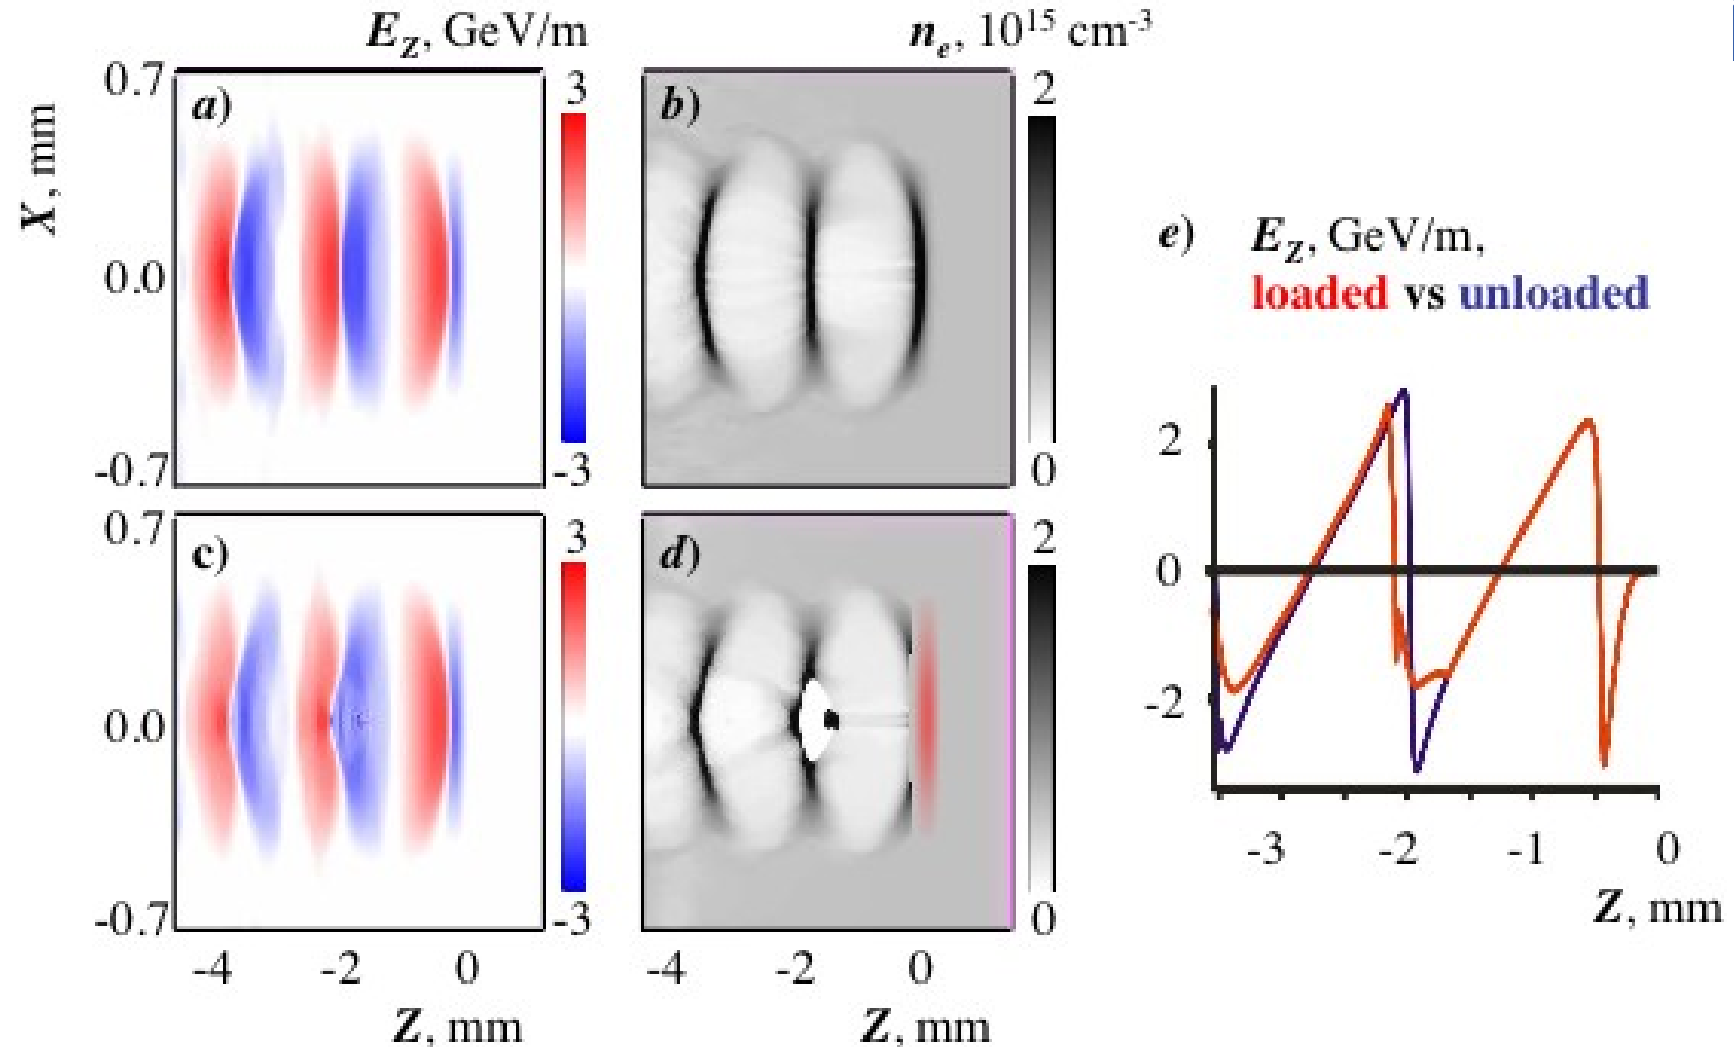

\* See e.g. R. Ruth et al., SLAC-PUB-3374, 1984

# Protons as Driver

- Unlike electrons, protons can be accelerated to very high energies using synchrotrons.
- With a 1 TeV p-driver an electron beam could be accelerated to up to 1 TeV in one single stage!
- Protons are positively charged.
  - They don't blow out the plasma electrons, they suck them in.
  - The general acceleration mechanism is similar.

# Density & Fields

A. Caldwell et al., Nature Physics 5, 363 - 367 (2009)

# Ideal Proton Beam

- Linear regime ( $N_b < n_0$ ):

$$E_{z,\max} \approx 2 \text{ GeV/m} \cdot \left( \frac{N_b}{10^{10}} \right) \cdot \left( \frac{100 \text{ } \mu\text{m}}{\sigma_z} \right)^2$$

- Available SPS Beam:

$$N_b \approx 3 \cdot 10^{11} \quad \sigma_z \approx 12 \text{ cm}$$

- Proton beam should to be compressed by four orders of magnitude!

# Magnetic Bunch Compression

G. Xia at LPWA09 in Kardamili, Greece, 2009

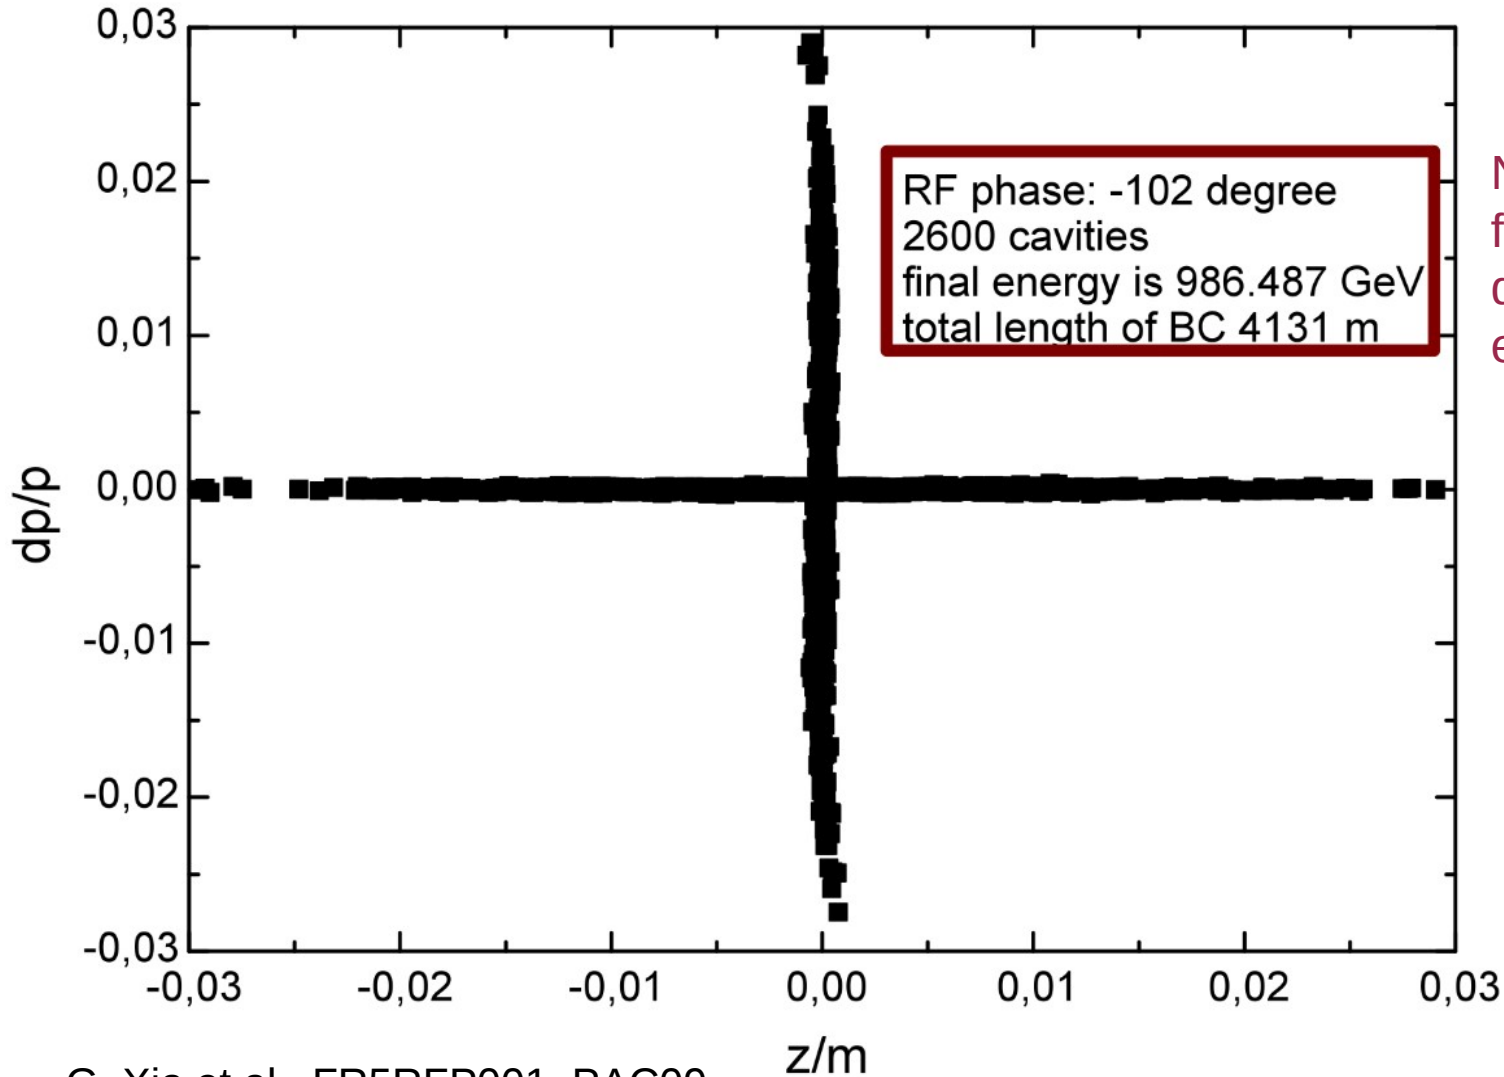

## □ Beam compression

- (1) by introducing an energy-position correlation along the bunch with an RF section at zero-crossing of voltage
- (2) and passing beam through a region where path length is energy dependent: this is generated by bending magnets to create dispersive regions.

- To compress a bunch longitudinally, trajectory in dispersive region must be shorter for tail of the bunch than it is for the head.

# Magnetic Bunch Compression

Not possible  
for a first  
demonstration  
experiment!

G. Xia et al., FR5RFP001, PAC09

# Self-modulated Proton Driver

- Production of short proton bunches not possible without major investment.
- Transverse two-stream instability can modulate a long bunch into micro bunches, naturally spaced in the right way to drive a strong wakefield.
- Studied both theoretically and numerically\*.

\* N. Kumar et al., PRL 104, 255003 (2010)

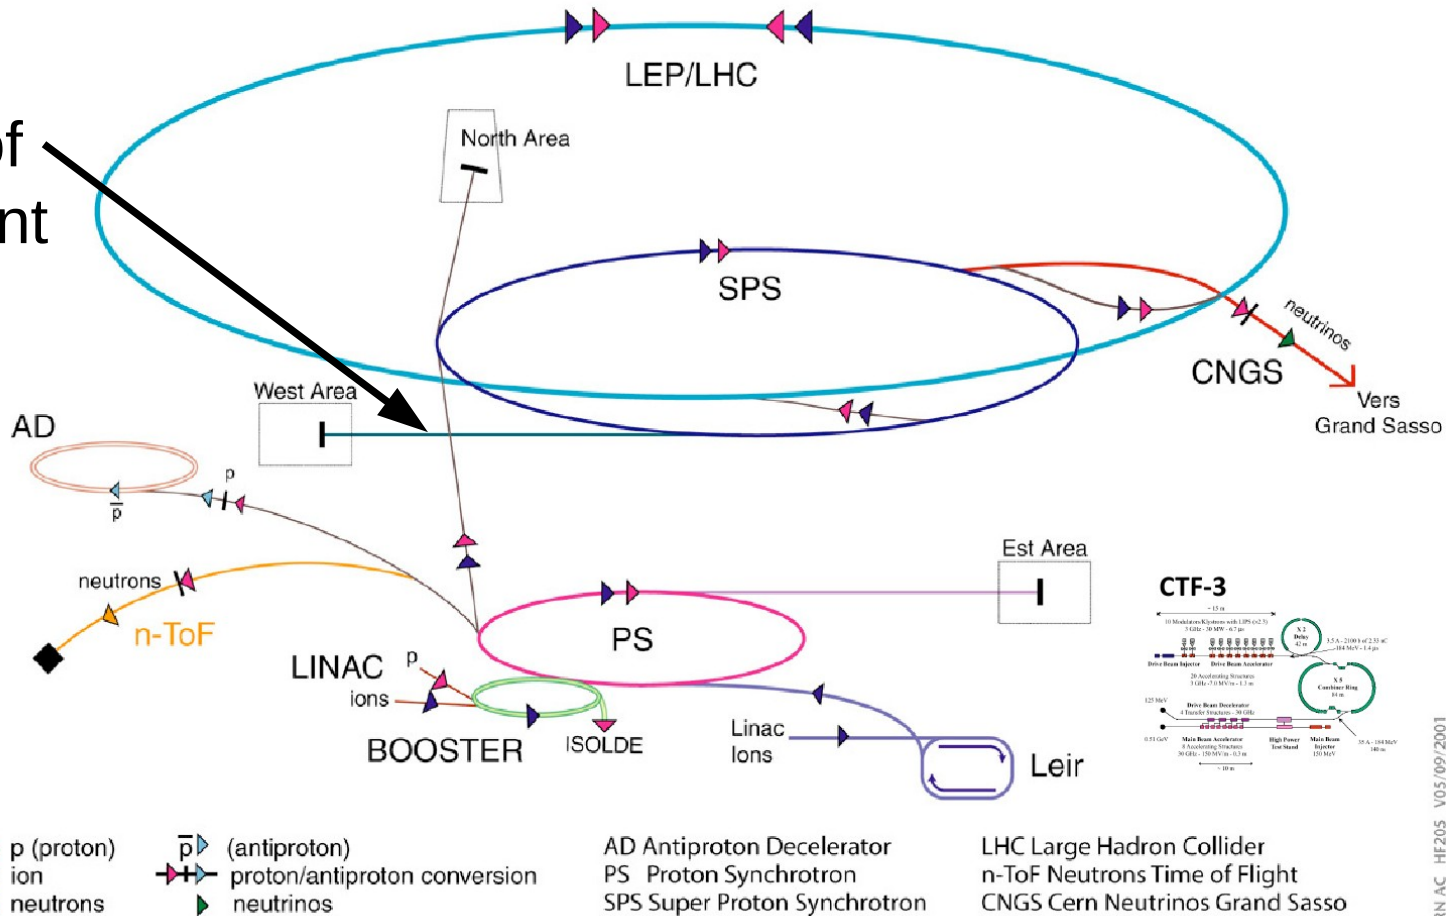

# What can CERN do?

- LWFA and PWFA ( $e^-$ ) well covered in research.
- No experiments on Proton-driven acceleration yet, but very promising for High Energy Physics!
- CERN has the needed p-beam infrastructure and resourced for an experiment.

# CERN Accelerators

## Accelerator chain of CERN (operating or approved projects)

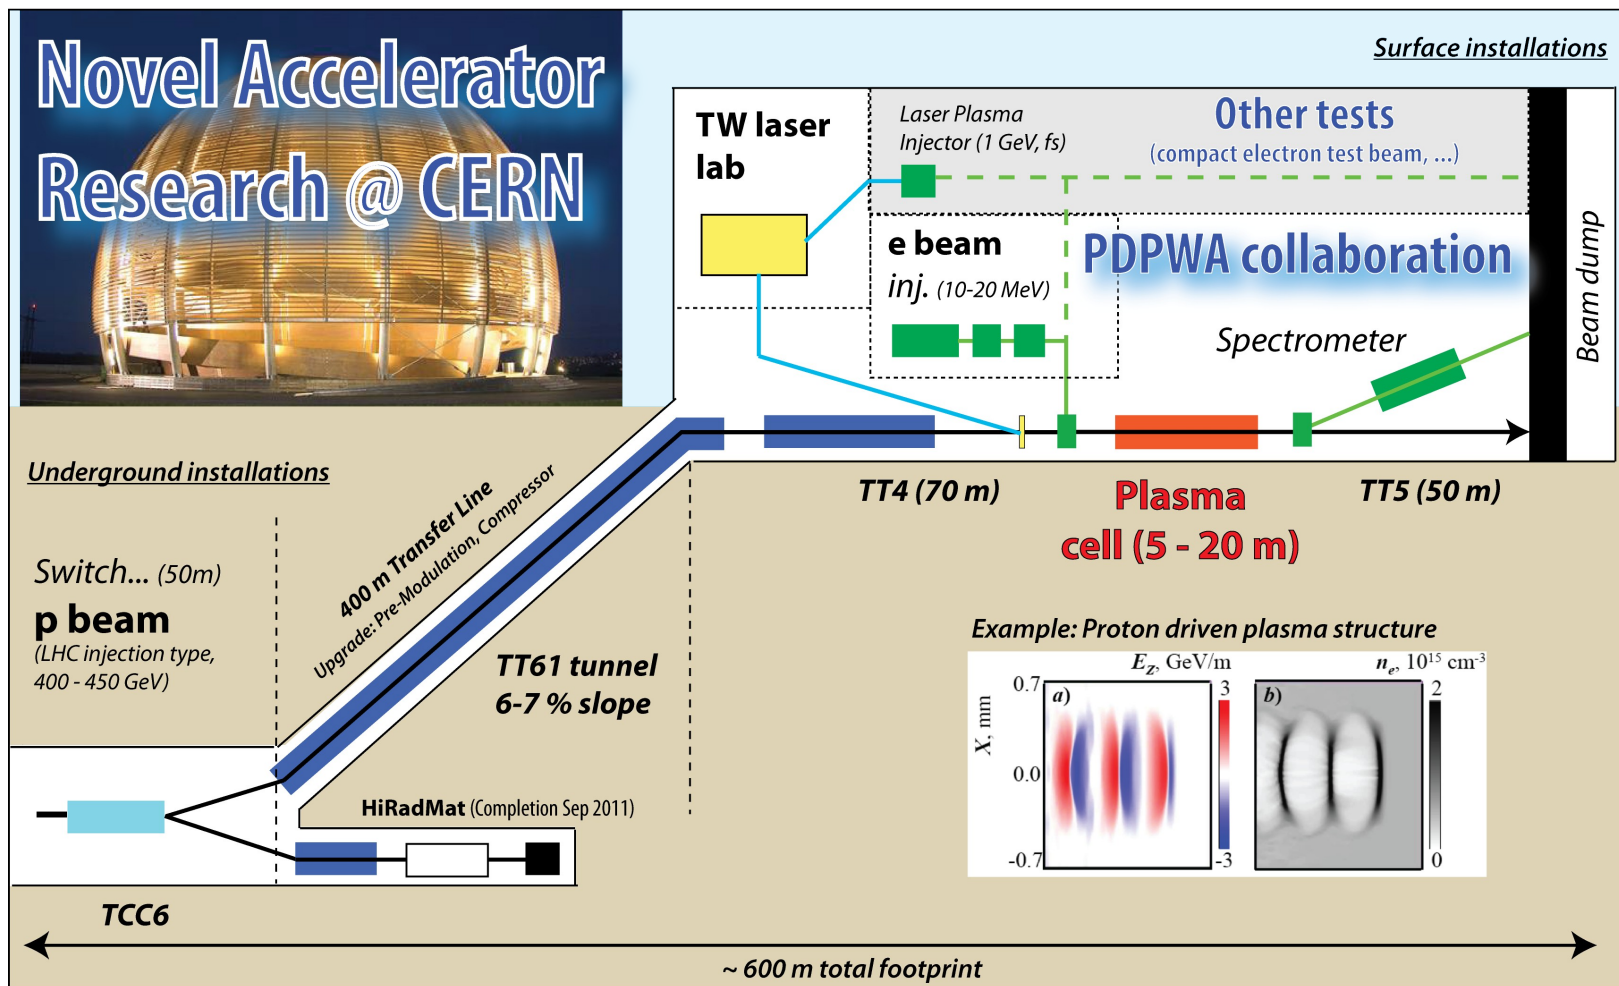

Planned location of experiment

CERN AC HF205 V05/09/2001

# Experiment Description

Picture: CERN-SPSC-2011-020 / SPSC-I-240

# Proton Beam Parameters

(Approximate)

- Beam type:  $p^+$  (Pb ions possible)
- Beam energy: 450 GeV
- Bunch intensity  $N_b$ :  $3 \times 10^{11}$
- Energy in Bunch: 8.5 kJ
- Number of bunches: 1
- Repetition rate: 0.03 Hz
- Energy spread: 0.03% (rms)
- Transv. Emittance: 3.3 – 3.5  $\mu\text{m}$  (normalized)  
6.9 – 7.3 nm (geometric)
- Radial. beam size: 0.2 mm (rms)
- Matched beta value: 1 m
- Bunch length: 12 cm (rms)

# Baseline Plasma Parameters

- Type of gas: Li
- Type of plasma cell: Laser ionized
- Plasma electron density  $n_0$ :  $\sim 10^{15} \text{ cm}^{-3}$
- Plasma diameter: few mm
- Plasma length: 5 – 10 m

# Experiment description

- Initial goal: Observe 1 GeV electron energy gain
- Develop plan for 100 GeV in 100m of plasma based on results

# Challenge: Phase Velocity of the Instability

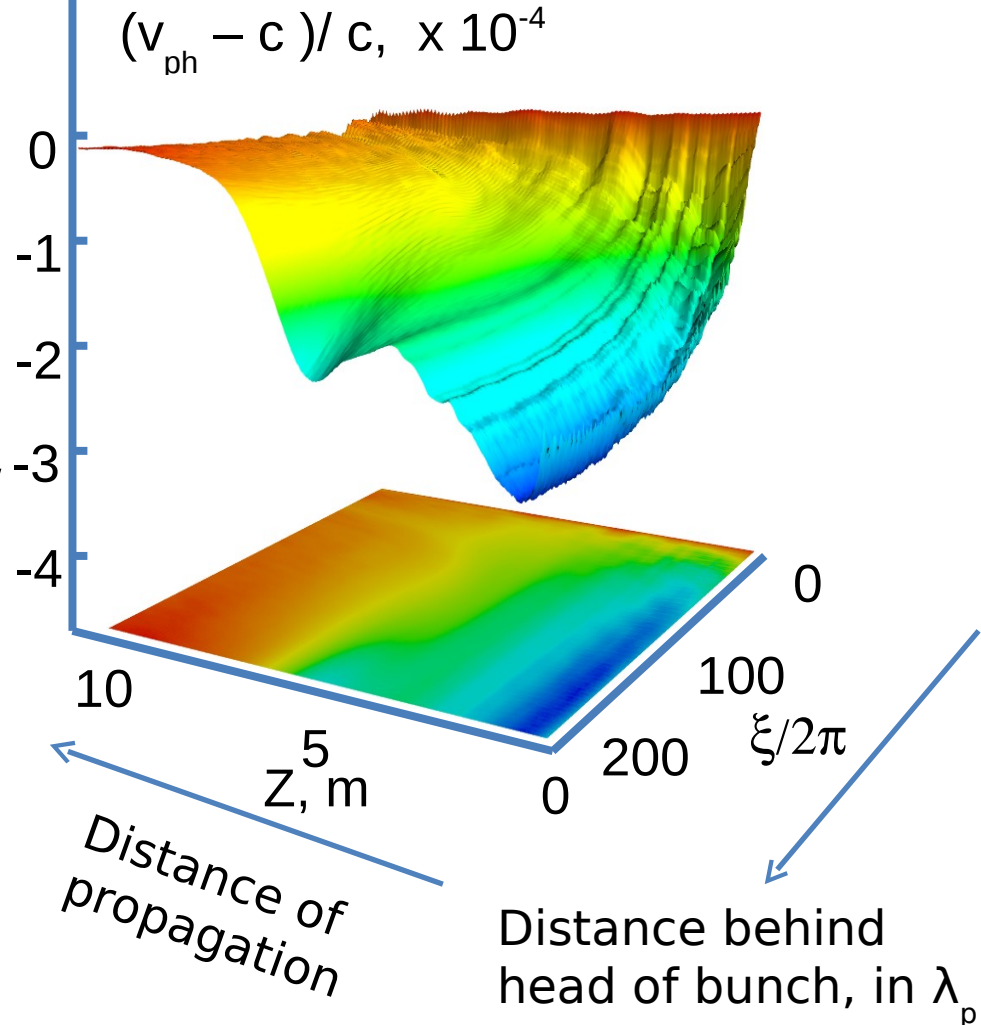

To trap & accelerate electrons in the wake of the protons, it is important that the wake phase velocity matches the electron velocity. Initially, the gamma-factor is

$$\gamma_{\min} \sim 40$$

This is order of magnitude below that of the beam.

Requires that we inject electrons after the phase velocity has stabilized.

Pukhov et al., PRL 107, 145003 (2011)

# Solution: Delayed Electron Injection

Pukhov et al., PRL 107, 145003 (2011)

Electron bunch injected off-axis at an angle, so that it merges with the proton bunch once the modulation is developed and the phase velocity is high.

# Expected Results

Long SPS drive beam will be sent into a 5-10m long plasma cell. Self-modulation of the beam occurs due to transverse wakefields. Produces many ultrashort beam slices.

Particle-in-cell simulations predict acceleration of injected electrons to beyond 1 GeV.

The modulation resonantly drives wakefields in the 100-1000 MV/m regime.

# Milestones

End 2012 (Conceptual Design report):

- Demonstrate at least one technology for a 1 m plasma cell with  $n_0 = 10^{14}-10^{15} \text{ cm}^{-3}$ , uniformity better than 5%
- Define seeding scenario in 3D simulations, define experimental test
- Technical design of e-beam injection into plasma, spectrometer, p-beamline
- Radiation and safety study
- Layout experimental area (beam delivery & dump, plasma cell, diagnostics, lasers)

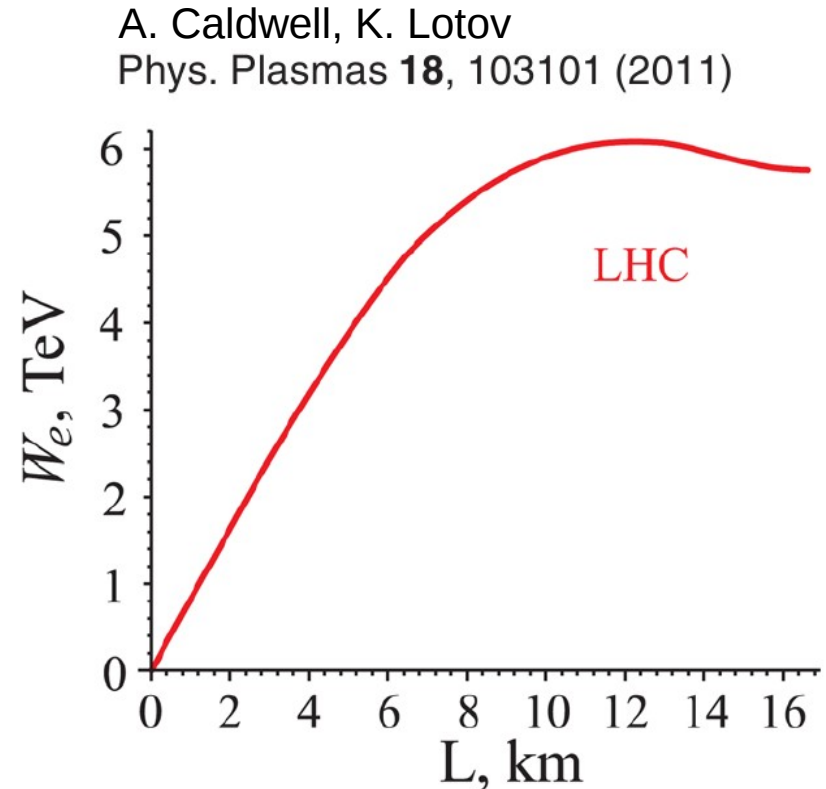

# Milestones - Continued

- End 2013:
  - Demonstrate 5 m plasma cell(s) with  $n_0 = 10^{15} \text{ cm}^{-3}$ , uniformity better than 2%
  - Demonstrate seeding in experiments
  - Define baseline choices
- End 2014:
  - Demonstrate completely operational plasma cell(s)
  - Installation of beam switch at end of LHC shutdown
- End 2015:
  - Installation of beam lines, experimental area
  - Beam commissioning, first beam to plasma

- Long term prospect:  
Modulated LHC beam
- Simulation results show  
electron energies of  
several TeV!
- No guiding magnetic fields  
necessary!

Strathclyde, KIT, UCL, D

Injector/spectrometer  
for electron bunch

# Seeding of instability

Slide: A. Caldwell - CERN Colloquium 2012

## Spontaneous instability

## vs Seeded instability

Original beam  
(front view)

Axisymmetric mode  
(half of the beam  
contributes to on-axis  
field excitation)

Hosing mode (small  
fraction of the beam  
contributes to the field  
at a given point)

No regular strong fields are possible  
with hosing

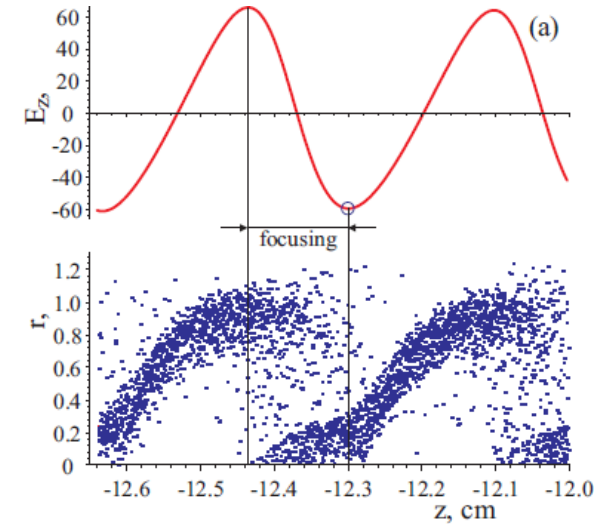

Instability seeding is necessary to  
produce the axially symmetric mode

# High Energy Outlook

Slide: A. Caldwell - CERN Colloquium 2012

- Wakefield amplitude drops quickly once beam is modulated.
- Reason: Defocusing regions move along bunch and destroy it.
- Remedy: Control of wake phase by plasma density profile.

# Issues with a Proton Driven PWA:

- Small beam dimensions required

$$eE_{linear} = 240(\text{MeV/m}) \left( \frac{N}{4 \cdot 10^{10}} \right) \left( \frac{0.6}{\sigma_z (\text{mm})} \right)^2$$

$$\sigma_z = 100 \mu\text{m}, N = 1 \cdot 10^{11} \text{ yields } 21 \text{ GeV/m}$$

Can such small beams be achieved with protons ?

Typical proton bunches in high energy accelerators have rms length  $>20$  cm

# Issues with a Proton Driven PWA:

- Phase slippage because protons heavy (move more slowly than electrons)

$$\delta = \frac{\pi L}{\lambda_p} \left[ \frac{1}{\gamma_{1i}\gamma_{1f}} - \frac{1}{\gamma_{2i}\gamma_{2f}} \right] \approx \frac{\pi L}{\lambda_p} \left[ \frac{M_p^2 c^4}{E_{driver,i} E_{driver,f}} \right]$$

$$L \leq \frac{1}{2} \left[ \frac{E_{driver,i} E_{driver,f}}{M_p^2 c^4} \right] \lambda_p \approx 300 \text{ m for } E_{driver,i} = 1 \text{ TeV}, E_{driver,f} = 0.5 \text{ TeV}, \lambda = 1 \text{ mm}$$

Few hundred meters possible but depends on plasma wavelength

## Issues with a Proton Driven PWA continued:

- Longitudinal growth of driving bunch due to energy spread

$$d = \Delta v \cdot t \approx \Delta\beta \cdot L = (\gamma_1^{-2} - \gamma_2^{-2})L \approx 2 \left( \frac{\Delta E}{E} \right) \frac{M_P^2 c^4}{E^2} L$$

$$\text{For } d = 100\mu\text{m}, \quad L = 100\text{m}, \quad E = 1.\text{TeV}, \quad \frac{\Delta E}{E} = 0.5$$

Large momentum spread is allowed !

# Issues - continued

## Proton interactions

$$\lambda = \frac{1}{n\sigma} < \frac{1}{n(10^{-23} \text{ cm}^2)} \quad n = 1 \cdot 10^{15} \text{ cm}^{-3} \quad \Rightarrow \quad \lambda = 1000 \text{ km}$$

Only small fraction of protons will interact in plasma cell

Biggest issue identified so far is proton bunch length.

Need large energies to avoid phase slippage because protons are heavy.

Large momentum spread is allowed.

# Experiment description

- Initial goal: Observe 1 GeV electron energy gain
- Develop plan for 100 GeV in 100m of plasma based on results

## Issues with a Proton Driven PWA:

- Small beam dimensions required

$$eE_{linear} = 240(\text{MeV/m}) \left( \frac{N}{4 \cdot 10^{10}} \right) \left( \frac{0.6}{\sigma_z(\text{mm})} \right)^2$$

$$\sigma_z = 100\mu\text{m}, N = 1 \cdot 10^{11} \text{ yields } 21 \text{ GeV/m}$$

Can such small beams be achieved with protons? Typical proton bunches in high energy accelerators have rms length >20 cm

- Phase slippage because protons heavy (move more slowly than electrons)

$$\delta = \frac{\pi L}{\lambda_p} \left[ \frac{1}{\gamma_{1i}\gamma_{1f}} - \frac{1}{\gamma_{2i}\gamma_{2f}} \right] \approx \frac{\pi L}{\lambda_p} \left[ \frac{M_p^2 c^4}{E_{driver,i} E_{driver,f}} \right]$$

$$L \leq \frac{1}{2} \left[ \frac{E_{driver,i} E_{driver,f}}{M_p^2 c^4} \right] \lambda_p \approx 300 \text{ m for } E_{driver,i} = 1\text{TeV}, E_{driver,f} = 0.5\text{TeV}, \lambda = 1\text{mm}$$

Few hundred meters possible but depends on plasma wavelength

# Summary

- Proton-driven plasma wakefield acceleration could yield high energy electrons without a need for staging.
- A demonstration experiment is planned at Cern.

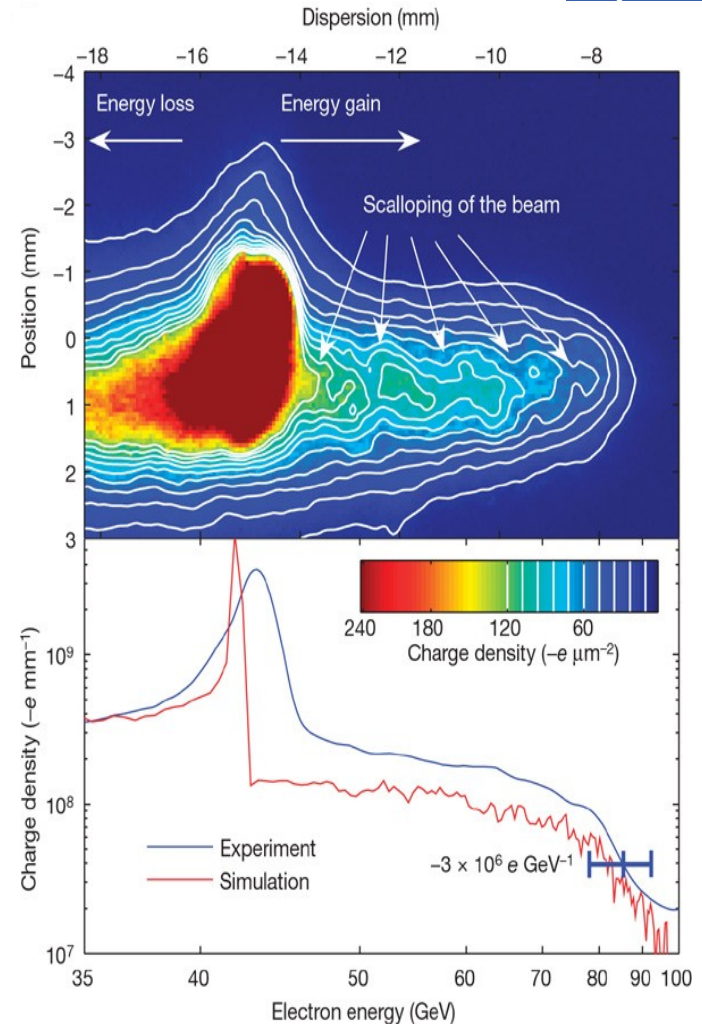

# PWFA – Problems for HEP

- Plasma does not accelerate by itself, only acts as a transformer.
  
- Energy gain of accelerated „witness“ bunch is limited by the energy of the driver (Laser or particle beam).
  
- I.e. to reach high energies one needs:
  - A driver with very high energy and / or
  - Staging of several acceleration modules.

# PWFA – Why?

- Plasmas can support very high fields without risk of material breakdown.
- Acceleration gradients of up to 100 GV/m have been demonstrated recently.\*
- This could reduce the length (and cost) of future accelerators by up to 3 orders of magnitude!

Energy doubling of 42 GeV  
 Electrons at SLAC

# Possible Experiment

- A proton beam will be extracted from the SPS and fired into a Lithium vapor oven.
- A co propagating Laser will generate a plasma in the middle of the (long) proton bunch.
- This way the plasma sees a proton bunch with a very sharp current flank.
- The instability seeded by this flank modulates the density of the proton bunch
- The modulated proton bunch creates plasma wakes.
- The resulting fields will be used to accelerate injected electrons.

# Plans for CERN Experiment

Map of electric fields in the plasma

- Within an international collaboration, protons as drives are studied.

Driving Proton Bunch

Accelerated Electron Bunch

- A Letter of Intent for a demonstration experiment has been submitted to SPSC\*.
