

TOTEM

TOTEM luminosity independent cross section measurements

Elastic cross sections

LHC optics estimation

Frigyés Nemes

Eötvös University

on behalf of the

TOTEM collaboration

<http://totem.web.cern.ch/Totem/>

Low-x Workshop, Paphos
2012, 27 June – 1 July

Experimental layout of the TOTEM experiment

Roman Pot stations

RP stations

- ◆ 2 units at about 5 m distance
- ◆ Measurement of very small proton scattering angles (few μrad)
- ◆ Vertical and horizontal pots mounted as close as possible to the beam
- ◆ BPM fixed to the structure gives precise position relative to the beam
- ◆ Overlapping detectors: relative alignment (10 μm inside unit between 3 RPs)

10 planes of edgeless detectors

Si edgeless detector

1 Roman Pot

LHC optics in brief

Proton position at a given RP (x, y) is a function of position (x^*, y^*) and angle (Θ_x^*, Θ_y^*) at IP5:

$$\text{measured} \left\{ \begin{pmatrix} x \\ \Theta_x \\ y \\ \Theta_y \\ \Delta p/p \end{pmatrix}_{\text{RP}} \right. = \begin{pmatrix} v_x & L_x & 0 & 0 & D_x \\ v'_x & L'_x & 0 & 0 & D'_x \\ 0 & 0 & v_y & L_y & 0 \\ 0 & 0 & v'_y & L'_y & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \left. \begin{pmatrix} x^* \\ \Theta_x^* \\ y^* \\ \Theta_y^* \\ \Delta p/p \end{pmatrix}_{\text{IP5}} \right\} \text{reconstructed}$$

The *effective length* and *magnification* expressed with the phase advance

$$L(s) = \sqrt{\beta(s)\beta^*} \sin \Delta\mu(s) \quad v(s) = \sqrt{\beta(s)\beta^{*-1}} \cos \Delta\mu(s) \quad \Delta\mu(s) = \int_0^s \beta^{-1}(s') ds'$$

Beam size and divergence at IP5 and RP

$$\sigma(x) = \sqrt{\varepsilon\beta_x} \quad \text{describes the spread of primary vertex and beam size at RP}$$

$$\sigma(\Theta) = \sqrt{\varepsilon/\beta_x} \quad \text{beam divergence @IP5 limits the angle measurement precision}$$

High $\beta^*=1535$ m target optics

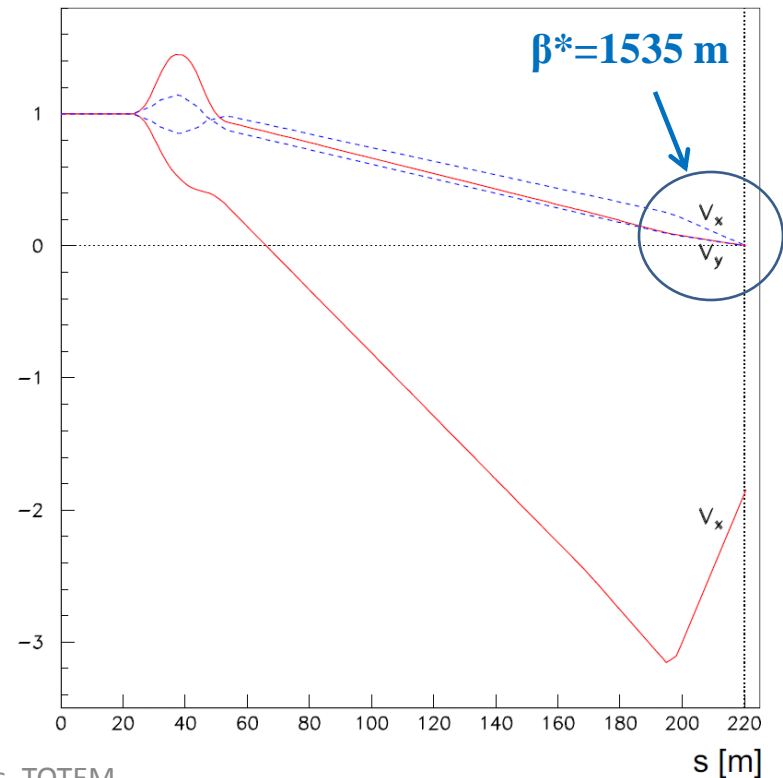

$\beta^* = 1535$ m is the *target* optics. Requires different injection optics. Properties:

- beam divergence $\sigma_{\theta^*} \approx 0.3$ μ rad, vertex size $\sigma_{IP} \approx 450$ μ m
- $\Delta\mu_{x,y} = \pi/2 \rightarrow v_{x,y} = 0$. Parallel-to-point focusing **eliminates** the large vertex contribution
- the large (270 m) vertical effective length L_y pushes protons vertically into RP acceptance
- acceptance in momentum transfer, $|t| > 2 \cdot 10^{-3}$ GeV², with $10 \sigma_{\text{beam size@RP}}$

Effective lengths from IP5 to RP @220 m

Magnification from IP5 to RP @220 m

LOW $\beta^*=3.5$ m OPTICS

Low $\beta^*=3.5\text{m}$ optics

Objective:

- to measure elastic scattering at high $|t|$

Properties of the optics:

- $\sigma_{IP} \approx 37 \mu\text{m}$ (magnification is not crucial)
- $L_x \approx 0, L_y = 22.4 \text{ m}$
- beam divergence $\sigma_{\theta^*} \approx 17\text{-}18 \mu\text{rad}$

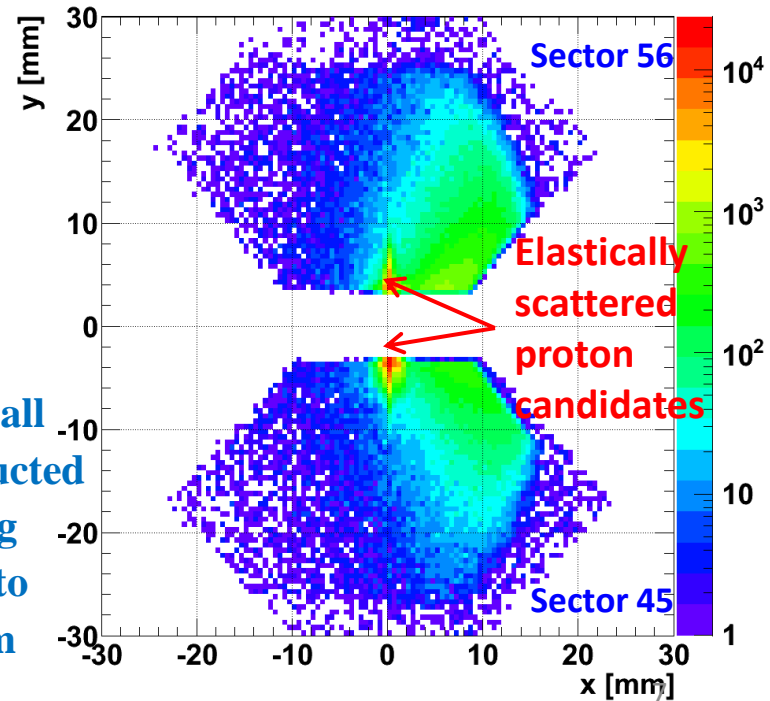

Data sources to improve our optics understanding:

- TIMBER database magnet currents
- FIDEL team conversion curves, implemented with LSA
- WISE field harmonics, magnet's displacements`

$$t = -p^2 \theta^2$$

$$\xi = \Delta p/p$$

The intercepts of all selected reconstructed tracks in a scoring plane transverse to the beam at 220 m

The effect of machine imperfections $\beta^*=3.5\text{m}$

Machine imperfections:

- Strength conversion error, $\sigma(B)/B \approx 10^{-3}$
- Beam momentum offset, $\sigma(p)/p \approx 10^{-3}$
- Magnet rotations, $\sigma(\phi) \approx 1 \text{ mrad}$
- Beam harmonics, $\sigma(B)/B \approx 10^{-4}$
- Power converter errors, $\sigma(I)/I \approx 10^{-4}$
- Magnet positions $\Delta x, \Delta y \approx 100 \mu\text{m}$

Perturbed element	$\delta L_{y,b1}/L_{y,b1} [\%]$
MQXA.1R5	0.98
MQXB.A2R5	-2.24
MQXB.B2R5	-2.42

MQY.4R5.B1	-0.10
MQML.5R5.B1	0.05
$\Delta p/p$	-2.19

Imperfections alter the optics !

Constraints from proton tracks in the Roman Pots $\beta^*=3.5\text{m}$

Optics imperfections can be determined from proton

tracks *measured* in the Roman Pots. The method is based on:

- elastic events are easy to tag
- the elements of the transport matrix are mutually correlated
- elastic scattering ensures that

$$\Theta_{y,b1}^* = \Theta_{y,b2}^*$$

$$\Theta_{x,b1}^* = \Theta_{x,b2}^*$$

$$\rightarrow R_1 \equiv \frac{\Theta_{x,b1,RP}}{\Theta_{x,b2,RP}} \approx \frac{dL_{x,b1,RP}}{ds} \frac{ds}{dL_{x,b2,RP}}$$

Matching the optics $\beta^*=3.5\text{m}$

On the basis of constraints R_1 - R_{10} the optics can be estimated.

$$\chi^2 = \sum_{i=1}^{10} ((R_{i,\text{measured}} - R_{i,\text{calculated}}) / \sigma(R_i))^2 + \chi_{\text{LHC Design}}^2$$

$$R_2 \equiv \frac{y_{b1, RP}}{y_{b2, RP}} \approx \frac{L_{y, b1, RP}}{L_{y, b2, RP}} \quad R_3 \equiv \frac{\Theta_{y, b1, RP}}{y_{b1, RP}} \approx \frac{\frac{dL_{y, b1, RP}}{ds}}{L_{y, b1, RP}}$$

$$R_7 \equiv \frac{X_{b1, RP}}{y_{b1, RP}} \approx \frac{m_{14, b1, \text{near_pots}}}{L_{y, b1, \text{near_pots}}} \quad R_5 \equiv \frac{X_{b1, RP}}{\Theta_{x, b1, RP}} \approx \frac{L_{x, b1, RP}}{dL_{x, b1, RP}/ds}$$

Monte-Carlo confirmation of the method (presented @IPAC 2012)

The Monte-Carlo study included the effect of:

- magnet strengths
- beam momenta
- displacements, rotations
- kickers, field harmonics
- elastic scattering Θ -distributions

Optical function relative error	Before		Matched	
	Mean [%]	RMS [%]	Mean [%]	RMS [%]
$\delta L_{y,b1}/L_{y,b1}$	0.77	3.0	$5.7 \cdot 10^{-3}$	$9.9 \cdot 10^{-2}$
$\delta (dL_{x,b1}/ds)/(dL_{x,b1}/ds)$	1.0	1.1	$-1.2 \cdot 10^{-1}$	$2.1 \cdot 10^{-1}$
$\delta L_{y,b2}/L_{y,b2}$	2.0	3.8	$1.5 \cdot 10^{-1}$	$9.5 \cdot 10^{-2}$
$\delta (dL_{x,b2}/ds)/(dL_{x,b2}/ds)$	-1.14	1.2	$-7.6 \cdot 10^{-2}$	$2.1 \cdot 10^{-1}$

Conclusion: for $\beta^*=3.5m$ TOTEM can measure the transfer matrix between IP5 and RPs with a precision

RMS <
0.2 %

Relative error distribution before and after matching

ELASTIC SCATTERING WITH $\beta^*=3.5$ m

Results (the **matched** L_y and dL_x/ds are used for reconstruction):

- RP approaches the beam down to $7 \sigma_{\text{beam size@RP}}$
- published in EPL **95** (2011) 41001
- $\xi \approx 0$

Collinearity Θ_x
Spread in agreement with beam divergence (17-18 μrad)

Collinearity Θ_y

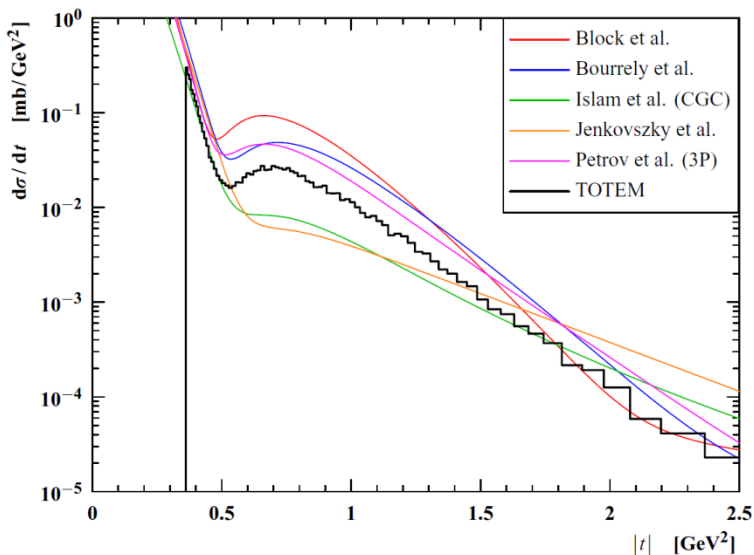

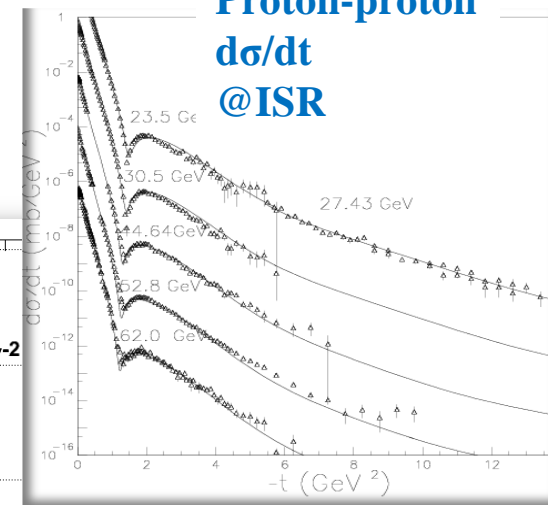

Final result: unfolded elastic scattering distribution $\beta^*=3.5m$

Published in EPL 95 (2011) 41001:

- $|t|$ range spans from 0.36 to 2.5 GeV^2
- below $|t| = 0.47 \text{ GeV}^2$ exponential $e^{-B|t|}$ behavior
- dip moves to lower $|t|$, proton becomes "larger"
- 1.5 - 2.0 GeV^2 power low behavior $|t|^{-n}$

Proton-proton
 $d\sigma/dt$
@ISR

The measured $d\sigma/dt$ compared with predictions of several models

HIGH β^* = 90 m OPTICS AND RESULTS

$\beta^* = 90$ m optics achievable using the standard LHC injection optics. Properties:

- $\sigma_{\Theta^*} = 2.5 \mu\text{rad}$, $L_x \approx 0$, $L_y \approx 260$ m
- vertex size $\sigma_{\text{IP}} \approx 212 \mu\text{m}$
- Acceptance: $|t| > 3 \cdot 10^{-2} \text{ GeV}^2$, RP distance from beam center $10 \sigma_{\text{beam size@RP}}$
- parallel to point focusing **only** in **vertical** plane @RP220

Effective lengths from IP5 to RP @220 m

The properties of the measured data:

- divergence is reduced with respect to 3.5 m optics (from 17-18 μrad to 2.5 μrad)
- lower background compared to 3.5 m ($< 0.1\%$)
- uncertainty of luminosity 4% (CMS)
- low intensity bunches and $\beta^*=90$ m \rightarrow no pile-up from single diffraction

Intermediate $\beta^*=90$ m optics: robustness

Objectives:

- First measurement of σ_{tot} elastic scattering in a wide $|t|$ range
- inclusive studies of diffractive processes
- measurement of forward charged multiplicity

Sensitivity of the effective length L_y :

- 1 ‰ perturbations magnet strength, beam momenta
- **Conclusion: not necessary to improve our understanding about $\beta^*=90$ m optics**

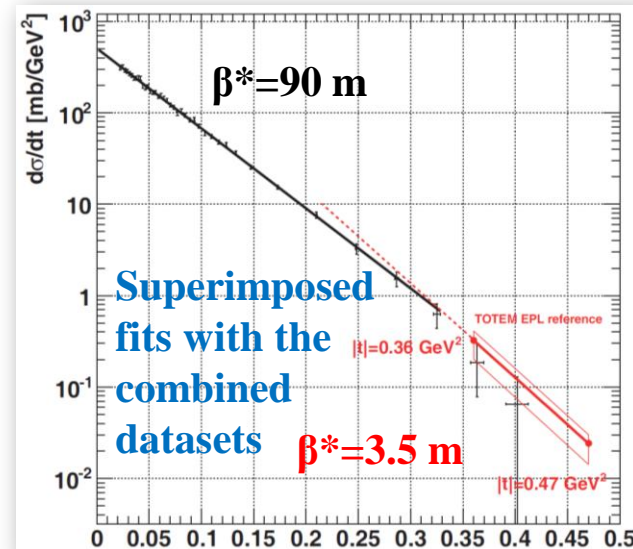

Perturbed element	$\delta_{L_{y,b1}}/L_{y,b1}$ [%]

Obtained $d\sigma/dt$ with $\beta^*=90$ m optics

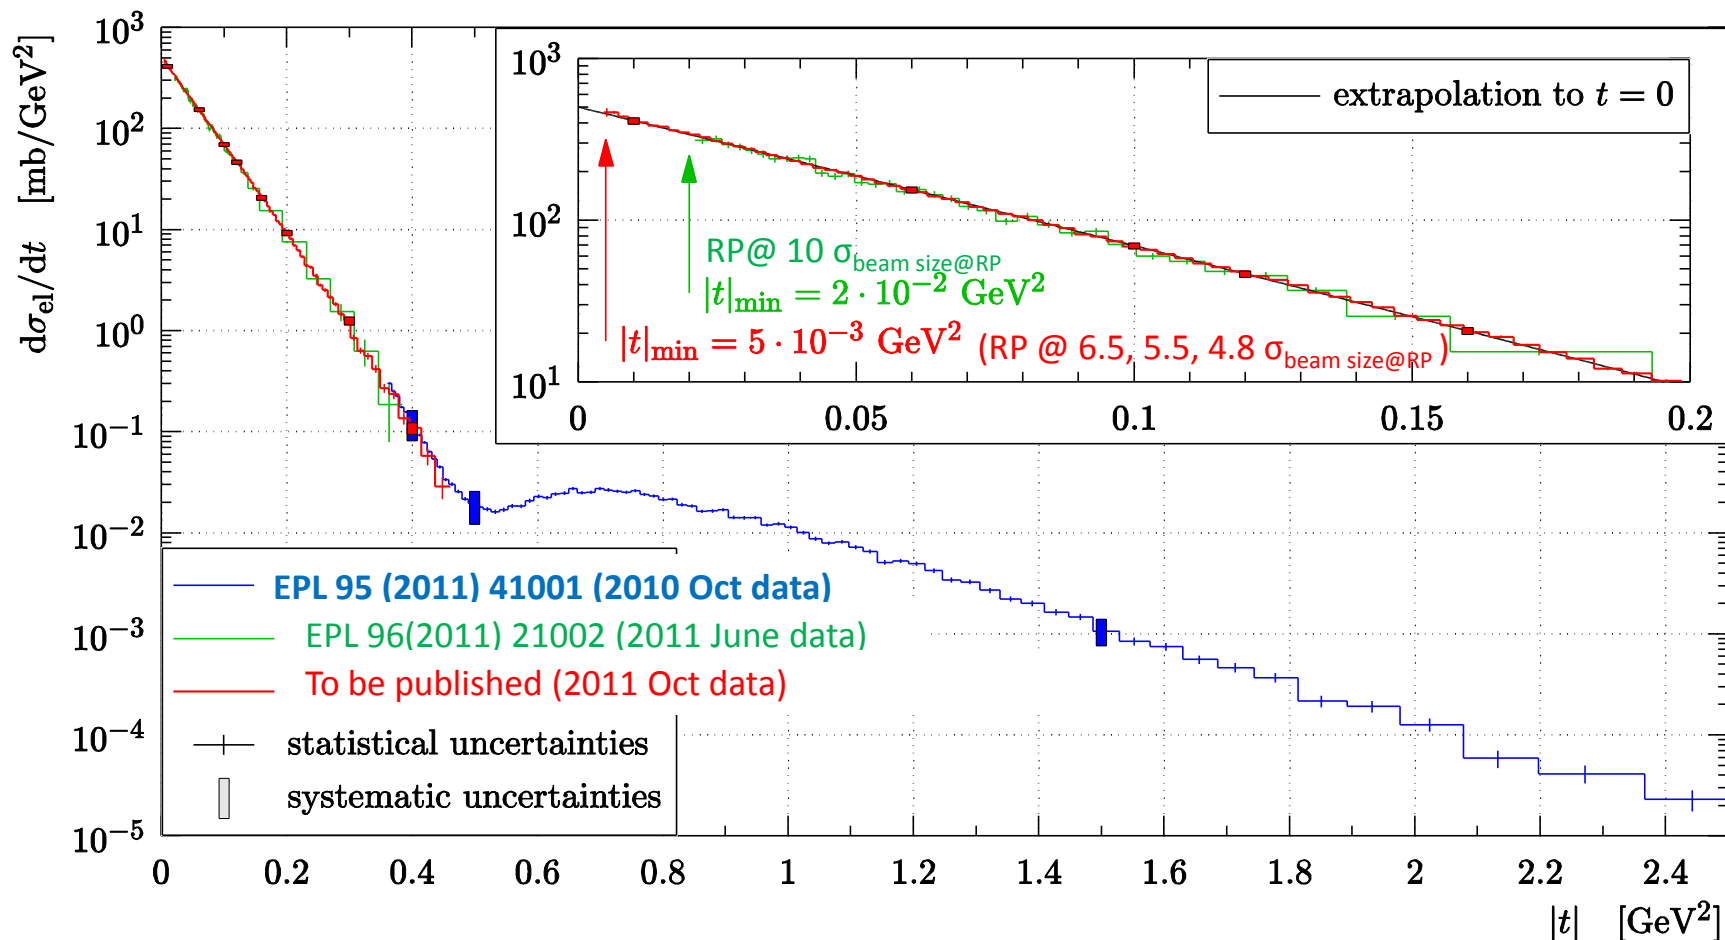

Published in EPL 96 (2011) 21002

Properties:

- $|t|$ range of the new set is 0.02 - 0.33 GeV^2
- $B = (20.1 \pm 0.2^{\text{stat}} \pm 0.3^{\text{syst}}) \text{GeV}^{-2}$ confirms that B increases with \sqrt{s}
- excellent agreement between the two measurements with different optics

Obtained $d\sigma/dt$ with the most recent result

Total Cross-Section with 4 methods

1. Low luminosity (CMS) + Elastic $d\sigma/dt$ + Optical th. (EPL 96(2011) 21002)

- depends on CMS luminosity for low-L bunches, elastic efficiencies and on ρ

$$\sigma_{tot}^2 = \frac{16\pi \hbar^2 c^2}{1 + \rho^2} \cdot \left. \frac{d\sigma_{el}}{dt} \right|_{t=0} \quad \sigma_{TOT} = 98.3 \quad 2.0 \text{ mb}$$

2. High luminosity (CMS) + Elastic + Optical theorem (to be published)

$$\sigma_{TOT} = 98.6 \quad 2.3 \text{ mb}$$

3. High luminosity (CMS) + Elastic + Inelastic (to be published)

- minimizes dependence on elastic efficiencies and **no dependence on ρ**

$$\sigma_{tot} = \sigma_{el} + \sigma_{inel} \quad \sigma_{TOT} = 99.1 \quad 4.4 \text{ mb}$$

4. Elastic ratios + Inelastic ratios + Optical theorem (to be published)

- Eliminates dependence on luminosity**

$$\sigma_{tot} = \frac{16\pi \hbar^2 c^2}{1 + \rho^2} \cdot \frac{\left. \frac{dN_{EL}}{dt} \right|_{t=0}}{N_{EL} + N_{INEL}} \quad \sigma_{TOT} = 98.1 \quad 2.5 \text{ mb}$$

Total Cross-Section with the luminosi

The result of the 4 methods on one plot:

Conclusions

- **TOTEM has measured the inelastic and elastic cross sections and the total cross section with the luminosity independent method at $\sqrt{s}=7$ TeV**
- Very soon these measurements will be repeated at $\sqrt{s}=8$ TeV
- Measurement of elastic scattering at very low- t and determination of the ρ parameter will be in reach during the high β ($\beta^*= 500$ m) run
- Several analyses on diffractive physics are going on, results are expected soon

Thank you for you attention !

Backup part

Luminosity calibration

TOTEM is able to determine the CMS luminosity:

- Elastic and inelastic rates are used

$$L = \frac{1 + \rho^2}{16\pi s} \cdot \frac{(N_{EL} + N_{INEL})^2}{dN_{EL} / dt \Big|_{t=0}}$$

Obtained luminosity values

October data : $L_{CMS} = 82.8 \mu b^{-1} \pm 4\%$

$L_{TOTEM} = 84.2 \mu b^{-1} \pm 3.8\%$

June data : $L_{CMS} = 1.65 \mu b^{-1} \pm 4\%$

$L_{TOTEM} = 1.655 \mu b^{-1} \pm 4.5\%$

Background and resolution determination $\beta^*=3.5\text{m}$

Signal to background normalisation
(also as a function of $\Delta\theta_y$)

$\sigma^* \rightarrow$ **t-reconstruction resolution:**

$$\frac{\sigma(t)}{\sqrt{t}} = \frac{\sqrt{2} p \sigma^*}{\sqrt{t}} : \begin{array}{l} 0.4 \text{ GeV}^2 : 14\% \\ 1 \text{ GeV}^2 : 8.8\% \\ 3 \text{ GeV}^2 : 5.1\% \end{array}$$

6/24/2012

Signal vs. background (t)

$|t|=0.4\text{GeV}^2$: $B/S = (11 \pm 2)\%$

$|t|=0.5\text{GeV}^2$: $B/S = (19 \pm 3)\%$

$|t|=1.5\text{GeV}^2$: $B/S = (0.8 \pm 0.3)\%$

t_y -acceptance corrections $\beta^*=3.5\text{m}$

Correction error (t_y):

- 0.31 GeV 2 : 30%
- 0.33 GeV 2 : 11%
- 0.35 GeV 2 : 2%
- 0.4 GeV 2 : 0.8%
- 0.5 GeV 2 : 0.1%

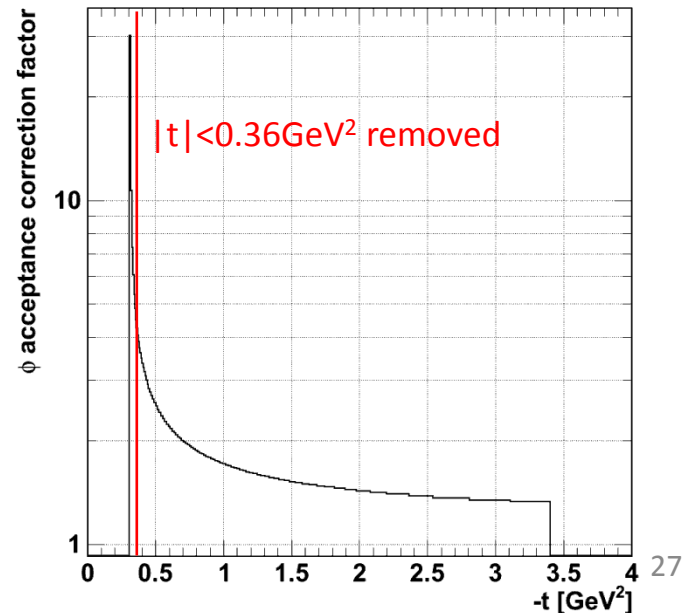

Acceptance corrections $\beta^*=3.5\text{m}$

Total φ -acceptance correction
