BROKEN SYMMETRIES AND THE MASSES OF GAUGE BOSONS

Peter W. Higgs

Tait Institute of Mathematical Physics, University of Edinburgh, Edinburgh, Scotland

(Received 31 August 1964)

“I certainly had no idea it would happen in my lifetime at the beginning, more than 40 years ago.

I think it shows amazing dedication by the young people involved with these colossal collaborations to persist in this way, on what is a really a very difficult task. I congratulate them.”

Peter Higgs, July 4th, 2012

Physics Letters B

Volume 716, Issue 1, 17 September 2012, Pages 1–29

Observation of a new particle in the search for the Standard Model Higgs boson with the ATLAS detector at the LHC ☆

Universally Available

Acknowledgements

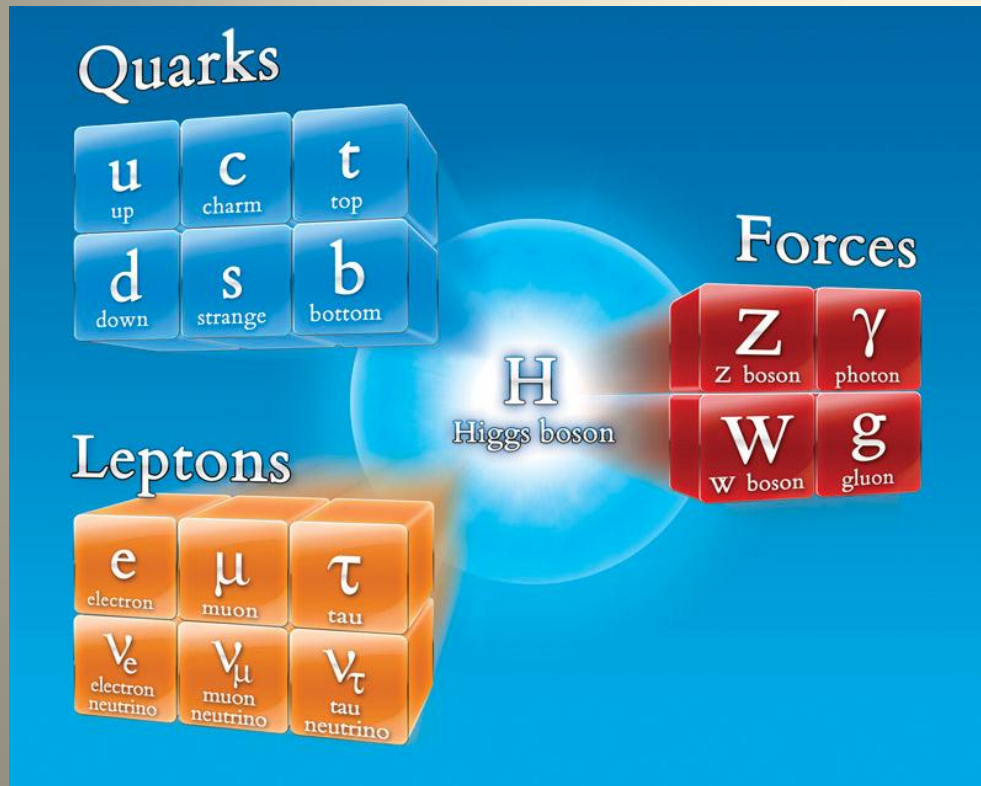

- This presentation rests on the shoulders of over 3000 ATLAS colleagues who built and operate the ATLAS detector, and who tirelessly analyze the data.
- The prerequisite for these studies was the seamless and astonishingly ever-improving performance of the Large Hadron Collider in 2011 and 2012.

Higgs Discovery

- The discovery of the Higgs particle would wrap up the Standard model in the most elegant and simple way
 - Light Higgs most natural, but opens up the possibility of the “Great Desert” (no new particles) up to the Planck scale – 10^{28} eV – 100 GeV is 10^{11} eV !
 - Measurement of Higgs properties a sensitive tool for probing New Physics

Large Hadron Collider

- Large Hadron Collider
 - proton-proton collider
 - Design c.m.s. energy **14 (2x7) TeV**, currently at **8 TeV**, **7 TeV** in 2011
 - Design luminosity **$10^{34} \text{ cm}^{-2}\text{s}^{-1}$** , **$7.7 \times 10^{33}$** achieved so far
- Why 7-8 (2x4) TeV ?
 - LHC in 27 km LEP tunnel (recycling)
 - Energy at r_{LEP} limited by superconducting magnets
 - $B_{max} = 8.3 \text{ T} \rightarrow E_{max} = 7 \text{ TeV}$
 - Following major incident in Sep'08 damaging ~50 magnets
 - 3.5, then 4 TeV considered safe
- Consolidation to design values during 2013(&14) break

LHC Performance in 2011

- The yearly plan at the Chamonix meeting (Jan'11) was $>1 \text{ fb}^{-1}$ per experiment
- 50 ns bunch spacing
- Due to increased peak luminosity up to $3.6 \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$ the final integrated luminosity surpassed 5 fb^{-1} by end of 2011
- Half of the luminosity ($\sim 2.5 \text{ fb}^{-1}$) was delivered in the final month of running

LHC Performance in 2012

- The yearly plan was
 - $>5 \text{ fb}^{-1}$ by end June
 - $\sim 15 \text{ fb}^{-1}$ by end of 2012 per experiment
- Peak luminosity increased up to $7.73 \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$
- $\sim 6 \text{ fb}^{-1}$ by end of June
 - $\sim 1.5 \text{ fb}^{-1}$ delivered in the final week – still the record
- 23.3 fb^{-1} total delivered
 - 21.7 fb^{-1} recorded by ATLAS

LHC Performance in 2013/14

- Heavy ion run until Feb 16 8:25
- End of LHC Run 1
- Entering consolidation shutdown for ~2 years
 - Change inter-magnet splices to allow running at 13-14 TeV
 - Upgrade collimation system
- Achieve design luminosity of $10^{34} \text{ cm}^{-2}\text{s}^{-1}$
- 25 ns bunch spacing
- Accumulate 50-100 fb^{-1} in 2018

ATLAS Detector

Venice, March 7, 2013

The Real Thing

Muon Spectrometer ($|\eta| < 2.7$): air-core toroids with gas-based muon chambers
 Muon trigger and measurement with momentum resolution $< 10\%$ up to $E_\mu \sim 1$ TeV

Length : ~ 46 m
 Radius : ~ 12 m
 Weight : ~ 7000 tons
 $\sim 10^8$ electronic channels
 3000 km of cables

3-level trigger
 reducing the rate
 from 40 MHz to
 ~ 200 Hz

Inner Detector ($|\eta| < 2.5$, $B=2T$):
 Si Pixels, Si strips, Transition Radiation
 detector (straws)

ATLAS p-p run: April-December 2012

Inner Tracker			Calorimeters		Muon Spectrometer				Magnets	
Pixel	SCT	TRT	LAr	Tile	MDT	RPC	CSC	TGC	Solenoid	Toroid
99.9	99.4	99.8	99.1	99.6	99.6	99.8	100.	99.6	99.8	99.5

EM calorimetry
 e/γ trigger
 E-resolution

All good for physics: 95.8%

Venice, March

Luminosity weighted relative detector uptime and good quality data delivery during 2012 stable beams in pp collisions at $\sqrt{s}=8$ TeV between April 4th and December 6th (in %) – corresponding to 21.6 fb^{-1} of recorded data.

Higgs Production @ LHC

Which haystack is the needle in ?

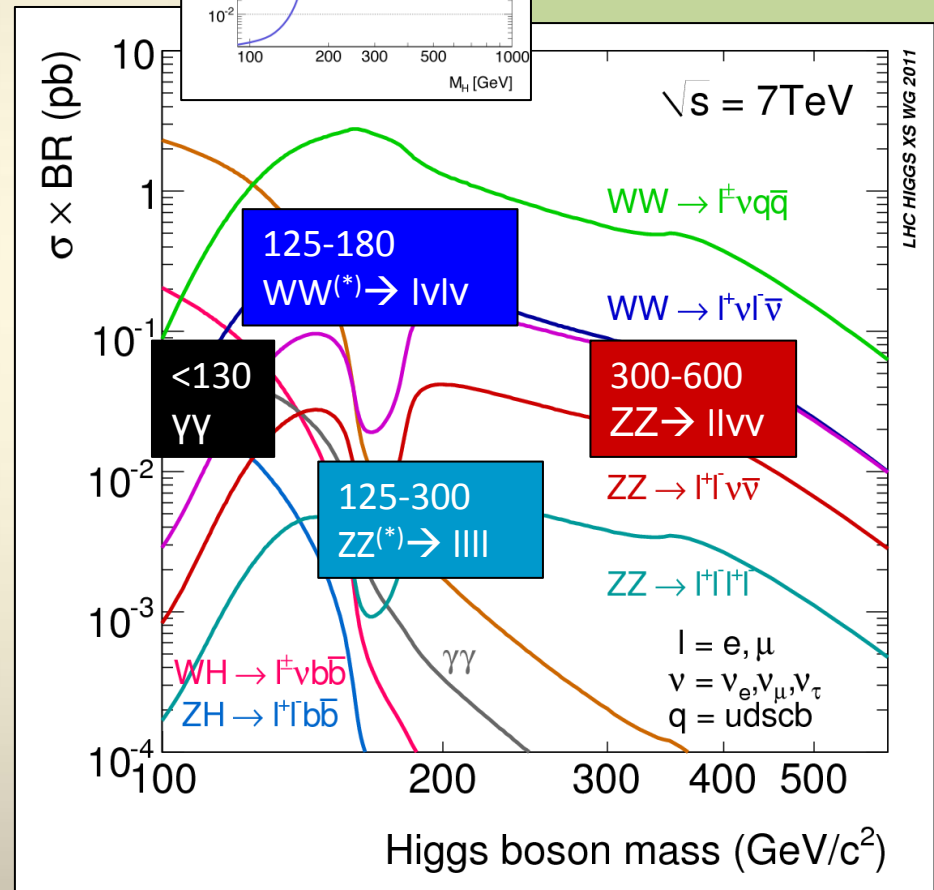

Higgs Decays

- Higgs decays determined by mass couplings
 - Decays to W, Z weak bosons dominate if kinematically allowed
 - One of the bosons can be virtual
 - For low masses two-photon, b-quark and tau decays
 - Two photons via loops

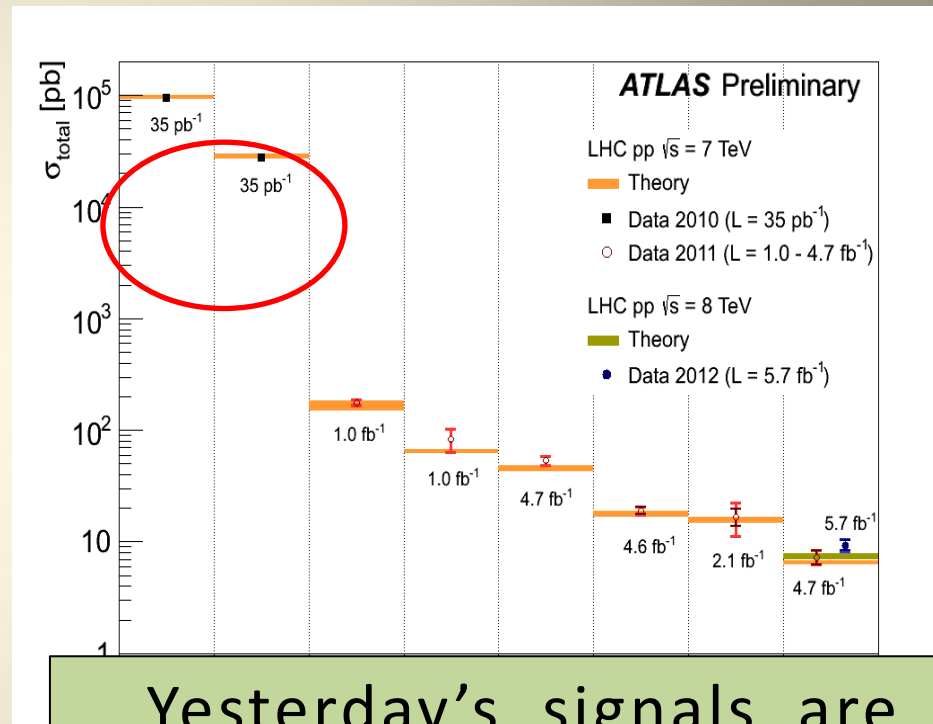

The faster it decays the less precise its mass (Heisenberg)

Higgs Detection @ LHC

- Rare process
 - Production only $\mathcal{O}(10^{-10})$ of total cross section
 - Further suppression by decay branching ratio
- Huge backgrounds
 - Need distinct event features
 - Leptons (e, μ) from W, Z
 - Energetic gamma rays
 - “Golden” channel: $H \rightarrow ZZ \rightarrow 4l$
 - $H \rightarrow ZZ \rightarrow 4l$ and $H \rightarrow \gamma\gamma$ can be fully reconstructed: H invariant mass, but $\sigma \times BR \mathcal{O}(10 \text{ fb})$
 - $H \rightarrow WW \rightarrow l\nu l\nu$ has two missing ν 's, $\sigma \times BR \mathcal{O}(100 \text{ fb})$
 - Need to understand how to model backgrounds
 - From data and Monte Carlo simulations

Yesterday's signals are today's backgrounds !
(100M W, 10M Z on tape)

Additional Burden – Pile-Up

- LHC still operates with 50 ns bunch spacing
 - ~ 1 collision per bunch crossing @ $L \sim 2 \times 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$
 - Up to >40 overlaid collisions at highest luminosity
 - Challenging environment - $\mathcal{O}(1000)$ tracks – demonstrating marvelous tracker performance
 - E.g. loose primary vertex constraint for $H \rightarrow \gamma\gamma$
 - Backgrounds even harder to control

Signal in Presence of Background

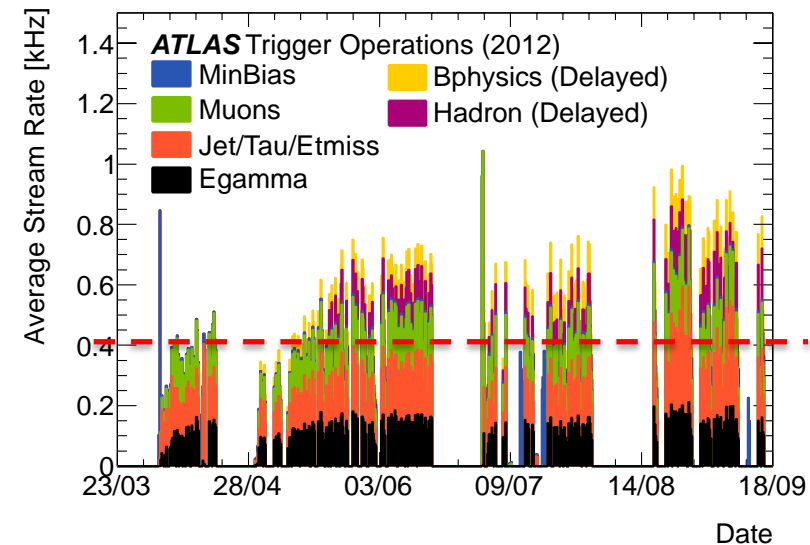

- Most powerful detection channels at low masses
 - $H \rightarrow WW^{(*)} \rightarrow l\nu l\nu$ (counting excess events)
 - $H \rightarrow ZZ^{(*)} \rightarrow 4l$ (H mass)
 - $H \rightarrow \gamma\gamma$ (H mass)
- } The Big Three
- All suffer from presence of background
 - Leptons from W, Z decays, QCD background
 - Small $\sigma \times BR$ results in small event samples
 - Downward fluctuation of signal can prevent detection
 - False negative (signal interpreted as background)
 - Upward fluctuation of background can mimic signal
 - False positive (background interpreted as signal)
 - Need careful, unbiased statistical treatment to assess

Sample Selection

- Initial event rate 20 MHz, (multiple collisions every bunch crossing)
- Three level trigger reduces this to 300-600 Hz of recorded events
 - Trigger focuses on energetic jets, leptons and photons thus efficiency high for relevant Higgs decays
 - Trigger composition changed on the fly during fill to match decreasing luminosity
- Offline sample selection
 - Based on identification of characteristic objects: electrons, muons, photons
 - Large and sometimes not well-known backgrounds estimated mostly with data-driven techniques using signal-free control regions

$$H \rightarrow WW^{(*)} \rightarrow \ell\nu\ell\nu$$

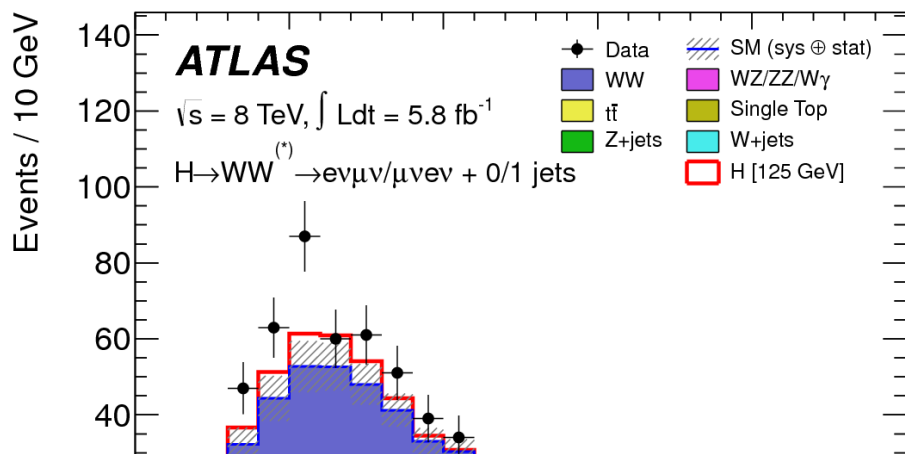

- Most sensitive channel $\sim 125\text{-}180\text{ GeV}$ ($\sigma \sim 200\text{ fb}$)
 - Challenging: two missing $\nu \rightarrow$ no mass reconstruction/peak \rightarrow “counting channel”
 - 2 isolated opposite-sign leptons, large $E_{T\text{miss}}$
 - Main backgrounds: WW, top, Z+jets, W+jets
 - $m_{\ell\ell} \neq m_Z$, b-jet veto, ...
 - topological cuts against “irreducible” WW background: $p_{T\ell\ell}$, $m_{\ell\ell}$, $\Delta\phi_{\ell\ell}$ (smaller for scalar Higgs), $m_{T\ell\ell}$ ($\ell\ell$, $E_{T\text{miss}}$)
- Worse pile-up in 2012
 - Main work-horse WW $\rightarrow e\nu\mu\nu$
 - Less background from Z, $\gamma^* \rightarrow \ell^+\ell^-$
 - Contributes 93% of WW sensitivity
- Counting \rightarrow crucial to understand background
 - Understanding of $E_{T\text{miss}}$ (genuine and fake)
 - Sensitive to pile-up !
 - Excellent understanding of background in signal region \rightarrow use signal-free control regions in data to constrain MC \rightarrow use MC to extrapolate to the signal region

H \rightarrow WW^(*) 2012 Sample

- No significant excess above expected background observed in 2011 WW \rightarrow l ν l ν data (Phys. Lett. B 716 (2012) 62-81)
- Final control plot of 2012 WW \rightarrow e ν μ ν data up to Oct12 (HCP set)
 - m_T used as control variable
 - Expected S/B in final 8 TeV sample still \sim 1:10 only
- Excess observed in 2012 data, consistent with a \sim 125 GeV Higgs

$$m_T = \sqrt{(E_T^{\ell\ell} + E_T^{\text{miss}})^2 - (\mathbf{P}_T^{\ell\ell} + \mathbf{P}_T^{\text{miss}})^2}$$

	Signal	WW	WZ/ZZ/W γ	$t\bar{t}$	$tW/tb/tqb$	Z/ γ^* + jets	W + jets	Total Bkg.	Obs.
H + 0-jet	45 ± 9	242 ± 32	26 ± 4	16 ± 2	11 ± 2	4 ± 3	34 ± 17	334 ± 28	423
H + 1-jet	18 ± 6	40 ± 22	10 ± 2	37 ± 13	13 ± 7	2 ± 1	11 ± 6	114 ± 18	141

Background Fluctuations

- Background is a random process, N_{bg} often well described by Poisson (Gauss) pdf
- The N - σ significance refers to probabilities of an excursion from the mean of relevant pdf
- For **exclusion** of signal presence, $\sim 2 \sigma$ downward fluctuation of expected S+B is taken, allowing for 5 % false negatives
- For detection of particles two landmarks on upward background fluctuation are agreed
 - 3σ : **evidence**, 0.13 % false positives
 - 5σ : **discovery**, $< 3 \times 10^{-7}$ false positives
- To bring background fluctuations into perspective
 - For a fair dice in a ludo game ~~background~~ background only
 - 1σ effect: \sim six in first trial
 - 2σ effect: \sim 2 consecutive sixes in a row
 - 3σ evidence: \sim 4 consecutive sixes in 2 trials
 - 5σ discovery: \sim 8 consecutive sixes in a row
- **When would you start suspecting someone is cheating ?**

H \rightarrow WW^(*) Results

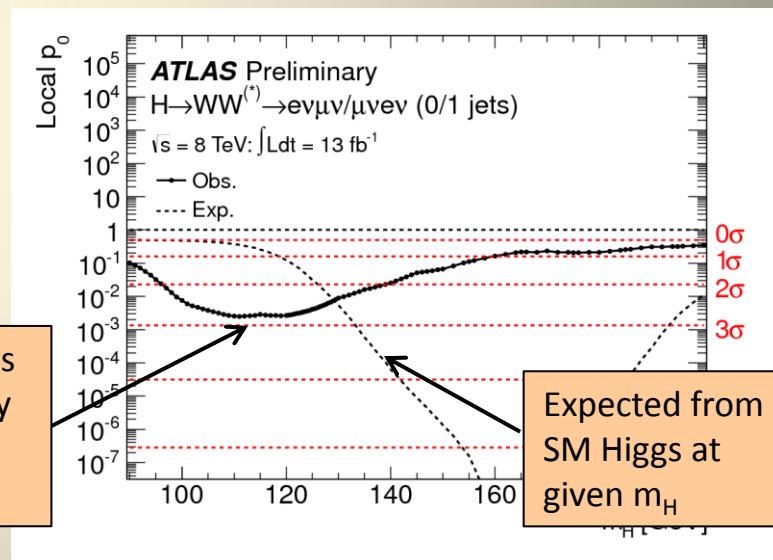

- 13 fb⁻¹ of 2012 data up to Oct

Exclusion of Higgs signal contents in units of σ_{SM} at 95 % C.L.

p_0 - consistency of data with background-only expectation

Poor mass sensitivity broadens range

Expected from SM Higgs at given m_H

- Excluded (95% CL): **139 GeV < m_H** (expected: **127 GeV !**)
- Excess **2.8 σ** (1.9 expected) over a broad range of **$m_H \sim 125$ GeV** (poor m_H resolution)

$H \rightarrow \gamma\gamma$

- Small cross-section: $\sigma \sim 40$ fb
- Simple final state: 2 high- p_T isolated photons
 - $E_T(\gamma_1, \gamma_2) > 40, 30$ GeV (20/20 for 7 TeV)
 - Main background: $\gamma\gamma$ continuum
 - irreducible, smooth, ..
- Events divided into 14 categories
 - 9 based on η -photon (e.g. central, rest, ...), converted/unconverted, $p_T^{\gamma\gamma}$ perpendicular to $\gamma\gamma$ thrust axis + VBF(2j) + VH (l, $E_{T\text{mis}}$, $2j_{\text{lowmass}}$)
- Crucial experimental aspects:
 - excellent $\gamma\gamma$ mass resolution to observe narrow signal peak above irreducible background
 - powerful γ /jet separation to suppress γj and jj background with jet $\rightarrow \pi^0$ faking single γ

Two-photon event

Two-photon with two jets

H → γγ Invariant Mass – γγ Angle

$$m_{\gamma\gamma}^2 = 2 E_1 E_2 (1 - \cos\alpha)$$

α = opening angle of the two photons

Use longitudinal (and lateral) segmentation of EM calorimeter to measure photon polar angle ϑ crucial at high pile-up: many vertices distributed over σ_z (LHC beam spot) ~ 5.6 cm \rightarrow difficult to know which one produced the $\gamma\gamma$ pair

Z-vertex as measured in $\gamma\gamma$ events after selection from calorimeter "pointing"

- ❑ Calorimeter pointing capability reduces vertex uncertainty from ~ 5.6 cm (LHC beam spot) to ~ 1.5 cm \rightarrow Contribution to mass resolution from angular term is negligible with calo pointing ($\gamma \rightarrow ee$ vertex also used)
- ❑ Robust against pile-up

H $\rightarrow\gamma\gamma$ Final Sample

- After all selections: kinematic cuts, γ identification and isolation
 - $\sim 145\text{k}$ events with $100 < m_{\gamma\gamma} < 160$ GeV observed in the 2011+2012 data
 - expected signal efficiency: $\sim 40\%$ for $m_H=125$ GeV
- $m_{\gamma\gamma}$ spectrum fit with
 - 4th order polynomial or exponential for background, depending on category
 - plus Crystal Ball + Gaussian for signal,
 - background determined directly from data

Main systematic uncertainties

Expected signal yield : $\sim 8/11\%$
H $\rightarrow\gamma\gamma$ mass resolution : $\sim 14\%$
Background modeling : $\pm 0.2\text{-}4.6/0.3\text{-}6.8$ ev.
(category, 11/12)

H → γγ Results

p_0 - consistency of data with background-only expectation

- Maximum deviation from background-only expectation observed for $m_H = 126.5$ GeV:
 - Local p_0 -value: $\sim 10^{-13}$ or **7.4 σ** at **126.5 GeV**
 - Expected from SM Higgs: $\sim 4.1 \sigma$
- Seeing more signal than expected from SM... upward fluctuation of the signal ?
- Single channel discovery, no big point in quoting exclusion...

$$H \rightarrow ZZ^{(*)} \rightarrow 4l$$

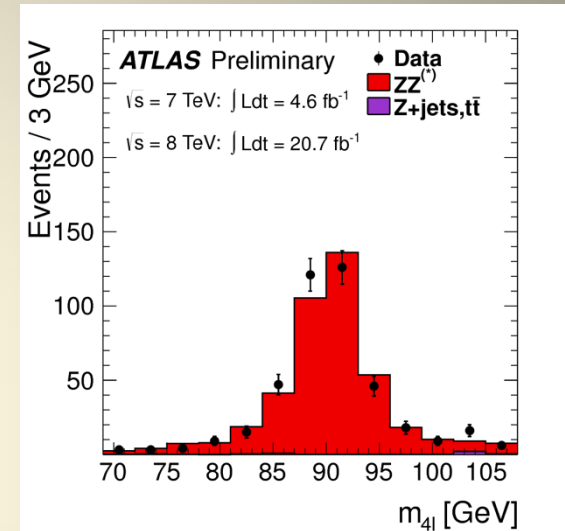

- $\sigma \sim 2\text{-}3$ fb only, however:
 - Mass can be fully reconstructed \rightarrow signal events cluster in a (narrow) peak
 - Pure: $S/B \sim 1$, narrow peak $\sigma \sim 2$ GeV
- Select 4 leptons: $p_T^{1,2,3,4} > 20, 15, 10, 7/6(e/\mu)$ GeV
 - $m_{12} = 50\text{-}106$ GeV; $115 > m_{34} > 12\text{-}50$ GeV (depending on m_{4l})
- Main backgrounds:
 - $ZZ^{(*)}$ (irreducible)
 - $m_H < 2m_Z$: Zbb , Z +jets, tt with two leptons from b/q -jets \rightarrow leptons
 - \rightarrow Suppressed with isolation and impact parameter cuts on two softest leptons
- Signal acceptance x efficiency: 15-37 % for $m_H \sim 125$ GeV
- Crucial experimental aspects:
 - High lepton reconstruction and identification efficiency down to lowest p_T
 - Good lepton energy/momentum resolution
 - Good control of reducible backgrounds (Zbb , Z +jets, tt) in low-mass region:
 - \triangleright Cannot rely on MC alone (theoretical uncertainties, b/q -jet \rightarrow I modeling, ..)
 - \triangleright Need to compare MC to data in background-enriched control regions (but: low statistics)

H → ZZ^(*) → 4l Performance

- ZZ^(*) → 4e, 4μ, 2e2μ
- Electrons
 - Identification efficiency from J/ψ → ee, W → ev, Z → ee data samples
 - Crucial to understand low-p_T electrons (affected by material) with data
 - H → 4e mass resolution: 2.5 GeV
 - Event fraction in ±2σ: ~ 80%
- Muons
 - Checked on Z → μμ data sample
 - Muon reconstruction efficiency > 95% over 4 < p < 100 GeV
 - H → 4μ mass resolution: ~1.6 GeV
 - Event fraction in ±2σ: ~ 85%

pp → Z → 4l
4l invariant mass peak

FSR corrected and
Z constraint fit

H \rightarrow ZZ^(*) \rightarrow 4l Final Sample

Events in $120 < m_{4l} < 130$ GeV

- After all selections:
 - kinematic cuts, isolation, impact parameter
- Mass range above 160 GeV
 - Observed: 317/59 events (8/7 TeV)
 - 301/53 background events expected
 - mainly from ZZ^(*)
- $m(4l) < 160$ GeV
 - Observed: 100/21 events (8/7 TeV)
 - Expected from background: 74/13
 - Significant excess clustered around 125 GeV
- $120 < m(4l) < 130$ GeV (containing $\sim 90\%$ of a $m_H=125$ GeV signal):
 - Similar contributions expected from signal and background: ~ 5 events each
 - S/B 1.9 (4 μ), 1.3 (2e2 μ), 1.1 (4e)
 - Background dominated by ZZ^(*) (4 μ), Z+jets and tt (2 μ 2e, 4e)
 - 32 events observed, 27 expected from SM S+B

2e2μ Event with $m_{2e2\mu} = 123.9 \text{ GeV}$

- 12 reconstructed vertices - \sim normal pile up in 2012
- $p_T(e,e,\mu,\mu) = 18.7, 76, 19.6, 7.9 \text{ GeV}$, $m_{ee} = 87.9 \text{ GeV}$, $m_{\mu\mu} = 19.6 \text{ GeV}$

H → ZZ^(*) → 4l Results

p_0 - consistency of data with background-only expectation

- Maximum deviation from background-only expectation observed for $m_H = 124.3$ GeV:
 - Local p_0 -value: 2.7×10^{-11} or 6.6σ
 - Expected from SM Higgs: $\sim 4.4 \sigma$
- (Another) single channel discovery

Wrapping it up – Combined Results

- Statistically combine data we talked ...

... and did not talk about

In a nutshell

- $\gamma\gamma$ and 4ℓ for complete 2011/12
 - $\sim 5+21 \text{ fb}^{-1}$
- WW 2012 up to Oct
 - $\sim 13 \text{ fb}^{-1}$
- bb and $\tau\tau$ 2011/Oct12
 - $\sim 5+13 \text{ fb}^{-1}$

A Bit of History

Entering Precision Higgs Physics

- With discovery well established in two separate channels
 - No need to push limit on SM signal presence
- Explore the newly discovered particle
 - Mass, signal strength
 - Production mechanisms
 - Spin
 - Couplings

Mass Measurement

- The two precision channels yield

$$m_H = 126.8 \pm 0.2 \text{ (stat)} \pm 0.7 \text{ (sys)} \text{ GeV} \quad H \rightarrow \gamma\gamma$$

$$m_H = 124.3^{+0.6}_{-0.5} \text{ (stat)} \text{ } ^{+0.5}_{-0.3} \text{ (sys)} \text{ GeV} \quad H \rightarrow 4\ell$$

- Best fit value

$$m_H = 125.5 \pm 0.2 \text{ (stat)} \text{ } ^{+0.5}_{-0.6} \text{ (sys)} \text{ GeV}$$

- Results still compatible at $\sim 1\%$ level ($\sim 2.5\sigma$)
 - Can depend critically on energy resolution modeling

$$\Delta \hat{m}_H = \hat{m}_H^{\gamma\gamma} - \hat{m}_H^{4\ell} = 2.3^{+0.6}_{-0.7} \text{ (stat)} \pm 0.6 \text{ (sys)} \text{ GeV}$$

Signal Strength

- All strengths relative to SM prediction
 - Evaluated at $m_H = 125.5$ GeV

Higgs Boson Decay	μ ($m_H = 125.5$ GeV)
$VH \rightarrow Vbb$	-0.4 ± 1.0
$H \rightarrow \tau\tau$	0.8 ± 0.7
$H \rightarrow WW^{(*)}$	1.4 ± 0.6
$H \rightarrow \gamma\gamma$	1.6 ± 0.3
$H \rightarrow ZZ^{(*)}$	1.5 ± 0.4
Combined	1.43 ± 0.21

– 2σ excess w.r.t. SM expectation

- Need more statistics before any claims can be made...

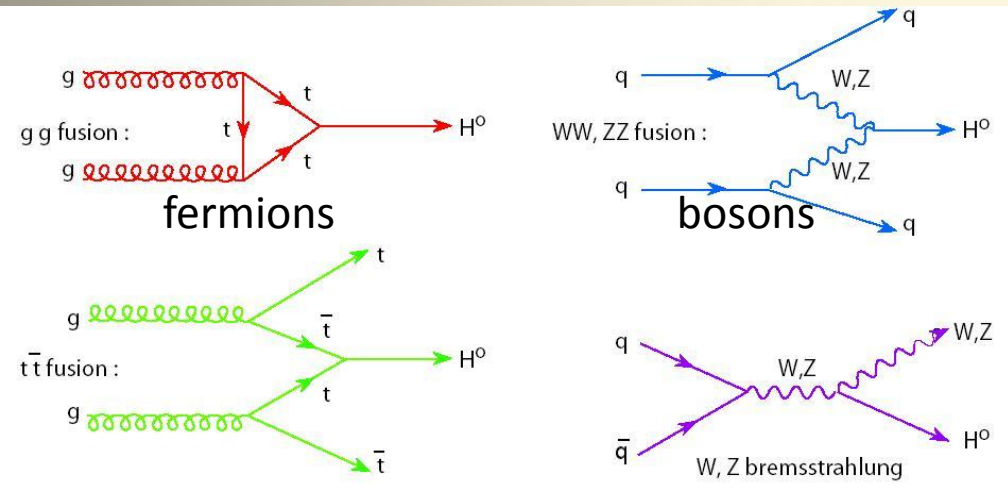

– No firm hint of coupling to fermions yet

Production Mechanism

- Dominant Higgs production mechanisms at LHC well defined in Standard Model
 - Results from $H \rightarrow \gamma\gamma$, $4l$, $\tau\tau$
 - Combine H couplings to fermions/bosons:
 - $ggF+ttH$; $VBF+VH$

Production relative to SM

- Result consistent with (high side of) SM predictions

Spin

- From decays the new particle is clearly a boson,
 - $H \rightarrow \gamma\gamma$ forbids $J=1$
- First measurements in $H \rightarrow \gamma\gamma$ and $H \rightarrow 4l$
 - $H \rightarrow \gamma\gamma$: photon angle relative to Higgs direction
 - Not yet approved for complete 2012 data-set
 - $H \rightarrow 4l$: Multivariate analysis: BDT, MELA
 - Problem: $J=2$ (graviton) model dependent

$H \rightarrow 4l$

		BDT analysis				J^P -MELA analysis			
		tested J^P for an assumed 0^+		tested 0^+ for an assumed J^P	CL_S	tested J^P for an assumed 0^+		tested 0^+ for an assumed J^P	CL_S
		expected	observed	observed*		expected	observed	observed*	
0^-	p_0	0.0037	0.015	0.31	0.022	0.0011	0.0022	0.40	0.004
1^+	p_0	0.0016	0.001	0.55	0.002	0.0031	0.0028	0.51	0.006
1^-	p_0	0.0038	0.051	0.15	0.060	0.0010	0.027	0.11	0.031
2_m^+	p_0	0.092	0.079	0.53	0.168	0.064	0.11	0.38	0.182
2^-	p_0	0.0053	0.25	0.034	0.258	0.0032	0.11	0.08	0.116

- SM value $J^P=0^+$ favoured over others, but exclusion level still small

The New Boson – What is it ?

- a) The Higgs boson (the One, SM) ?
- b) A Higgs boson (one of many, e.g. MSSM) ?
- c) An impostor (sth else) ?
- The Standard Model Higgs boson has a rich and well-defined associated phenomenology
 - Cross section, branching ratios
 - Spin, parity, couplings, self coupling
- All this needs to be explored in detail before providing a definite answer
- We have just started to enter the exploration regime for this new particle
 - The quest has just begun with remarkable results already available
 - LHC will deliver at least 10x if not 100x more data in its lifetime
- Exploring the new discovery in detail will take time, resources, and might require a new (linear ?) collider

Summary

- We have analysed up to 4.9 fb^{-1} of 7 TeV and up to 21 fb^{-1} of 8 TeV pp collision data for presence of SM Higgs boson
 - Across the 110-600 GeV mass region
 - In many distinct decay channels (3 most relevant for 2012 data)
- We observe an excess of events centred at $m_H \sim 125 \text{ GeV}$:
 - Excess comfortably exceeds discovery limit in two distinct, high-precision channels: $H \rightarrow \gamma\gamma$ (7.5σ) and $H \rightarrow ZZ^* \rightarrow 4l$ (6.3σ)
 - SM Higgs expectation: $4.1/4.2 \sigma$
 - Best mass value: $+125.4 \pm 0.6 \text{ GeV}$
 - Signal strength relative to SM: 1.45 ± 0.22
- We are entering precision Higgs physics
 - Started on spin and production mechanisms

No matter whether this particle turns out the Higgs, a Higgs or something exotic, we have set an important milestone in unveiling the very secrets of Nature

Backup

H → $\gamma\gamma$ Backgrounds

- Potentially huge background from γj and jj production with jets fragmenting into a single hard π^0 and the π^0 faking single photon
 - Suppressed by fine lateral segmentation (4mm η -strips) of the first compartment of ATLAS EM calorimeter
 - Need suppression of $\mathcal{O}(10^{-4})$ to get to level of irreducible $\gamma\gamma$ background
- After all cuts: $\sim 120\text{k}$ events with $100 < m_{\gamma\gamma} < 160$ GeV observed in the 2012 data
- Sample composition estimated from data using control samples
 - ✓ $\gamma j + jj \ll \gamma\gamma$ irreducible (purity 75%)
