Gamma: 0.5801 mrad/mm

Ion: Au-197 (32+)  
Energy: 393934 keV

RMS emittance: 8.161 mm·mrad  
Norm. RMS emittance: 0.5351 mm·mrad

Alpha: -0.9981  
Beta: 3.983 mm/mrad  
Gamma: 0.5012 mrad/mm

Ion: Au-197 (32+)  
Energy: 393934 keV

## Emittance calculations

Rod Keller's formula for ion source (no magnetic field):

$$\varepsilon = \pi r_i \sqrt{\frac{T_i}{E_i}} \quad \xrightarrow{\text{EBIS application}} \quad \varepsilon = \pi r_i \sqrt{\frac{K \Delta U_{beam}}{\Delta U_{accel}}}$$

$r_i$  = radius of ion system (80% of intensity),  $T_i$  – ion temperature

$K=0.1$  (?) (B. Penetrante, R. Marrs).

Good for small beam sizes, where effect of magnetic field is small.

Inclusion of the magnetic field effect:

$$\varepsilon = \pi \frac{r_{beam}}{\sqrt{2U_{extr}}} \left[ Br_{beam} \sqrt{\frac{q_i}{m_i}} + \sqrt{\frac{q_i B^2 r_{beam}^2}{4m_i} + \frac{\rho_l}{2\pi\varepsilon_0}} \right] \quad \text{Fredrik Wenander}$$

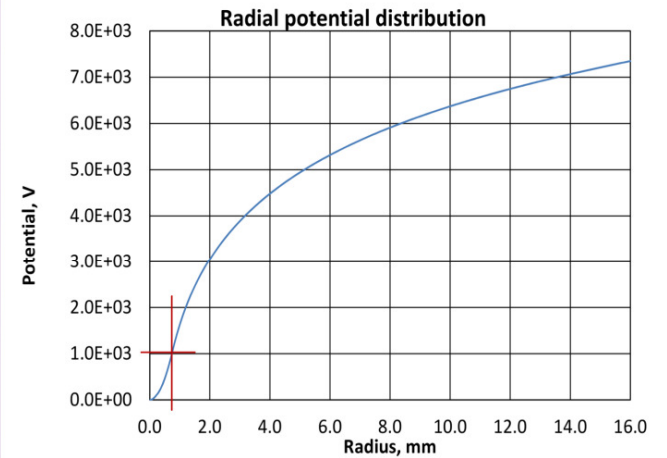

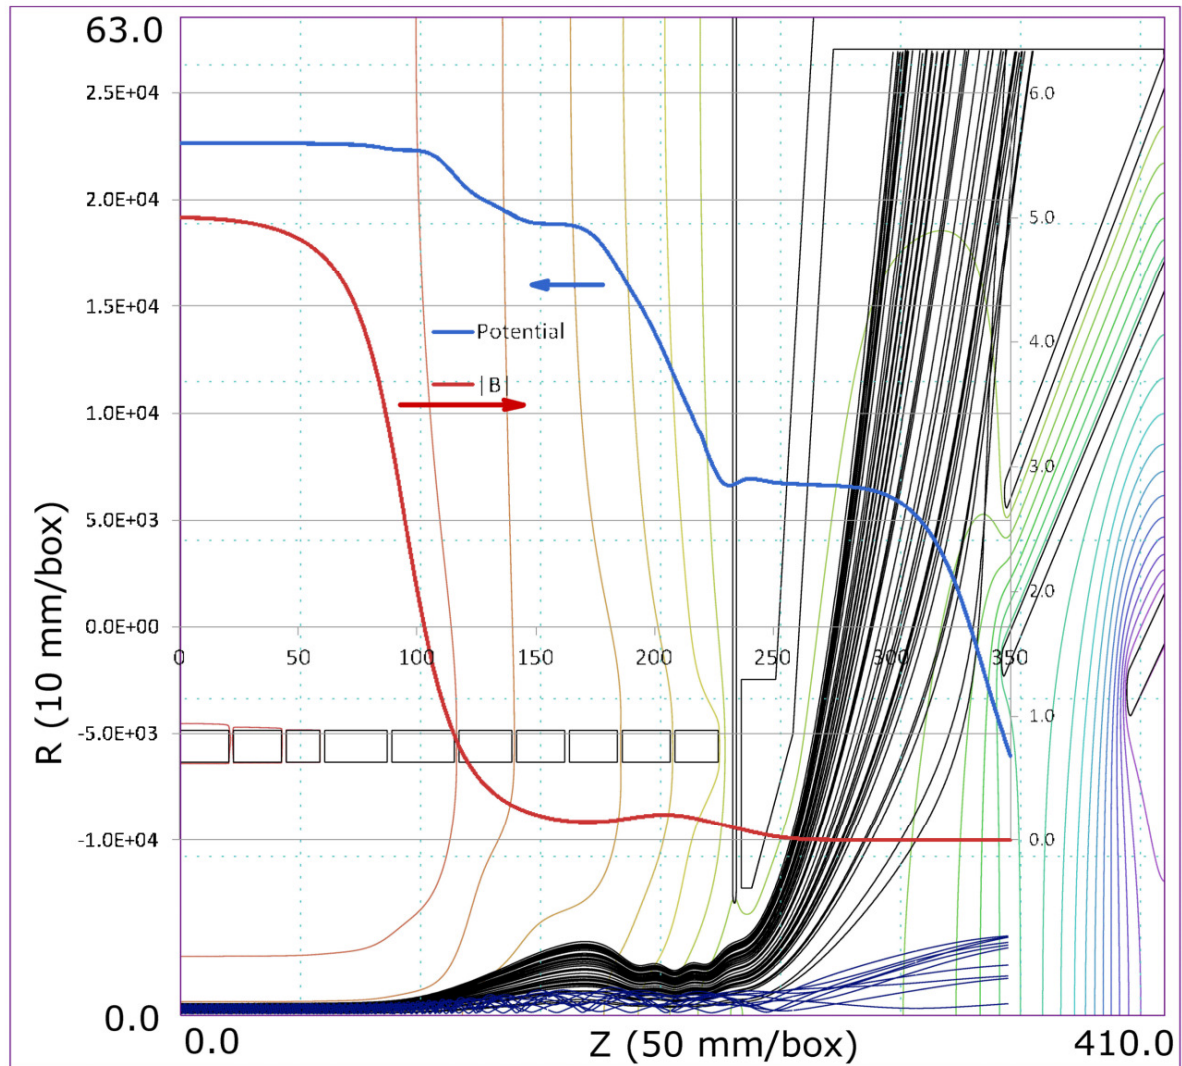

$$\varepsilon_B = \varepsilon_{B=0} \left[ 1 + \frac{1}{2} \frac{r_i}{r_c} \right] \quad r_c = 0.14 \frac{\sqrt{AT_i}}{r_c} \text{ (cm)} \quad \text{Ross Marrs}$$

$$\varepsilon = \pi r_i \left[ \sqrt{\frac{K \Delta U_{beam}}{\Delta U_{accel}}} + \frac{q_i B r_i}{p_i} \right] \quad \text{Formula with inclusion ion deflection in M-field}$$

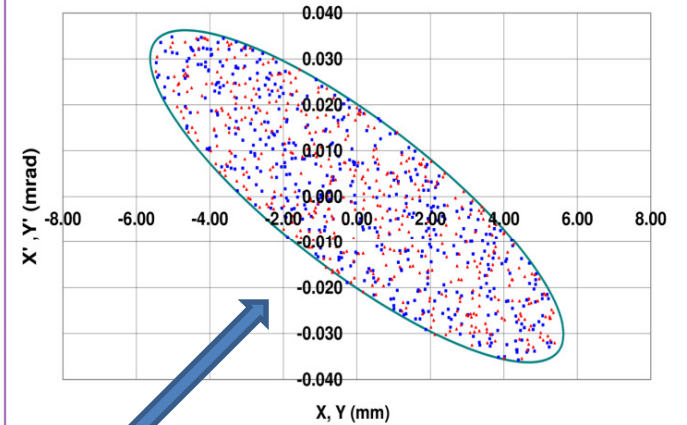

$p_i$ -ion momentum at exit,

All units in SI

# Ion injection simulation model

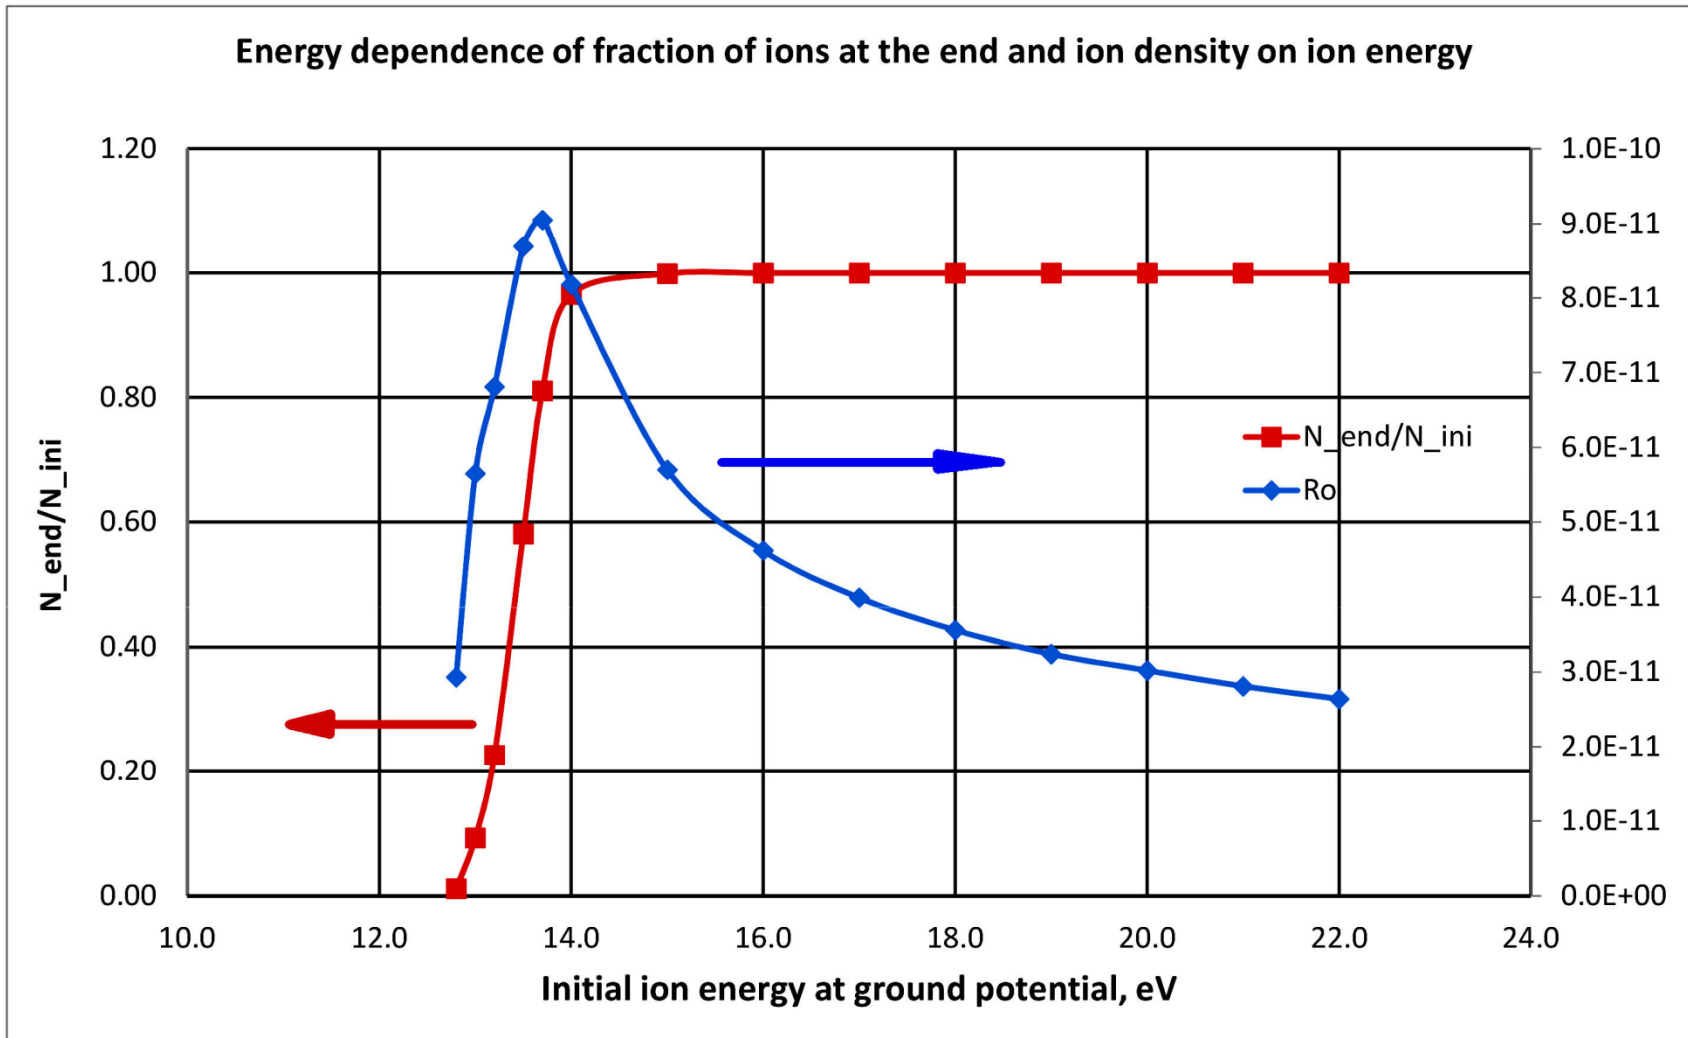

Ion beam emittance for  $r_{ion\_trapSr\_el\_beam}$  (0.75mm),  
 RMS  $e_x e_y = 0.0606 \text{ mm}^2 \text{ mrad}$ ,  $I_{el} = 10 \text{ A}$ ,  $E_{el} = 20 \text{ keV}$ ,

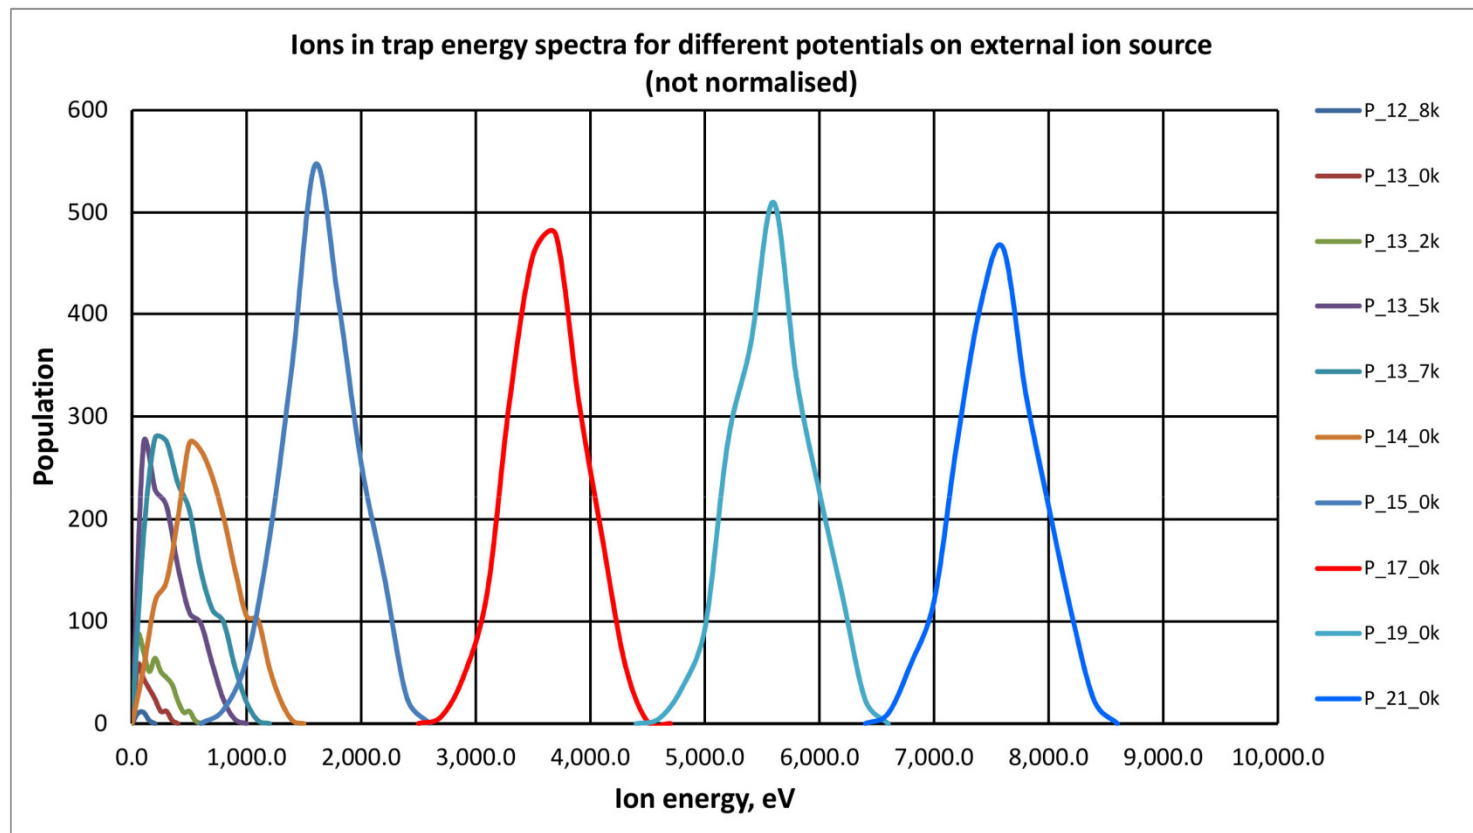

$$r_i \leq r_{el}$$

# Effect of ion energy on efficiency and final ion density

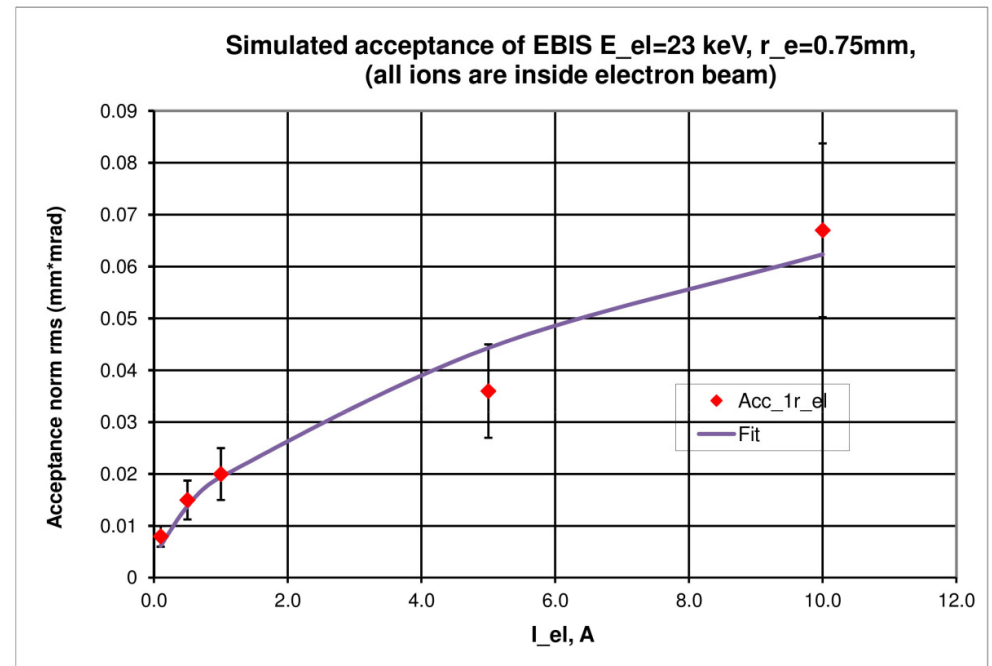

## Energy spectra of injected ions (simulated)

## Simulation result

No injected ion trajectories come out of electron beam boundary):

Fitting formula for emittance (normalized RMS):

$$\varepsilon(\text{mm} \cdot \text{mrad}) = 2.6 \cdot 10^{-3} \cdot r_b [\text{mm}] \cdot \sqrt{\Delta U_b (\text{V})}$$

For RHIC EBIS, 10A, 22 keV,  $\varepsilon=0.062$  mm\*mrad

# Test EBIS experiment with ANL

## Emittance of Cz1+ ion beam

Distortion in horizontal benders:

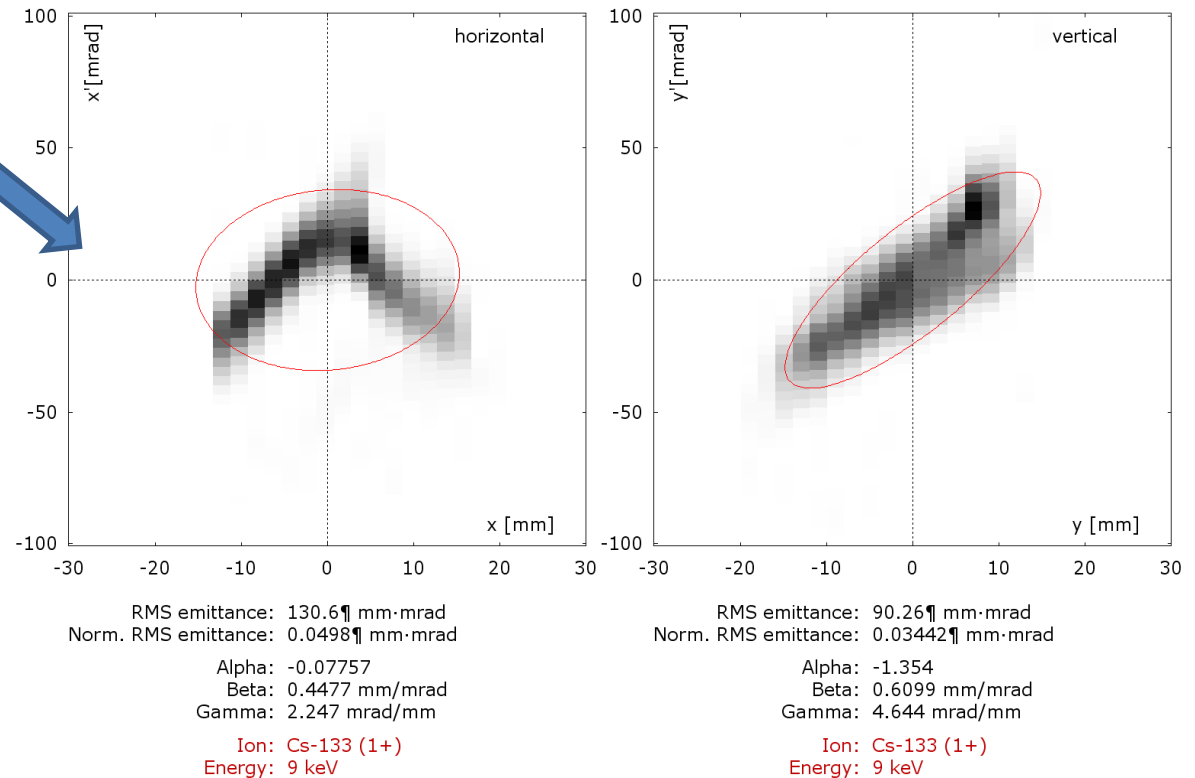

Test EBIS parameters:

$E_{el} = 20 \text{ keV}$

$I_{el} = 1.0 \text{ and } 1.5 \text{ A}$

Possible reasons for differences with simulated acceptance:

1. Distortion of the ion beam emittance of the injected beam
2. 1.0 A: good tuning, actual acceptance is higher because of trapping some of out-of-beam ions (allowed for low neutralization)
3. 1.5A: not sufficient tuning

e-beam current, A	$\epsilon_{inj}$ (mm·mrad)	$A_{sim}$ (mm·mrad)	Measured efficiency	Expected efficiency
1.0 A	0.04	0.027	0.75	0.68
1.5 A	0.04	0.033	0.71	0.82
