

# Selected event reconstruction algorithms for the CBM experiment at FAIR.

S. Lebedev<sup>1,3</sup>, A. Lebedev<sup>2,3</sup>, C. Hoehne<sup>1</sup> and G. Ososkov<sup>3</sup>  
<sup>1</sup>Giessen University, <sup>2</sup>Frankfurt University, <sup>3</sup>LIT JINR

# The CBM experiment: “electron” and “muon” setups

**CBM will provide hadron and lepton identification in large acceptance, good momentum and secondary vertex resolution**

Electron setup

**electron ID: RICH & TRD**

Muon setup

**muon ID: MUon Chamber**

# Challenges for event reconstruction

## Peculiarities for CBM:

- ▶ **Large track and ring densities and multiplicities**
  - ▶ up to 1000 charged particles per reaction in +/- 25°
- ▶ **High reaction rate**
  - ▶ up to 10 MHz
- ▶ **Track reconstruction**
  - ▶ large material budget
  - ▶ complex detector structure, overlapping sensors, dead zones
- ▶ **Ring reconstruction**
  - ▶ Different number of hits in rings (5 – 35)
  - ▶ Elliptic shape of the rings ( $B/A = 0.9$ )

Central Au+Au collision at 25 AGeV (UrQMD + GEANT3)

→ **fast reconstruction algorithms are essential**  
radical speedup: optimization and parallelism

# TRD and MUCH detectors

## **TRD:** Tracking and electron identification

### **Layout:**

- ▶ 10 layers starting at 5 m from the target.
- ▶ Rectangular pads, resolution: 300-500  $\mu\text{m}$  across and 3-30 mm along the pad.

## **MUCH:** Muon identification

### **Layout:**

- ▶ 18 GEM stations.
- ▶ First absorber 60 cm C + 5 Fe absorbers 20-20-25-35-100 cm.

# Track reconstruction in TRD and MUCH

- ▶ Two main steps:
  - ▶ Tracking
  - ▶ Global track selection

## Tracking is based on

- ▶ Track following
- ▶ Initial track seeds from STS
- ▶ Kalman Filter
- ▶ Validation gate
- ▶ Hit-to-track association techniques: nearest neighbor and branching
- ▶ Missing hits

## Track propagation

- ▶ Inhomogeneous magnetic field: solution of the equation of motion with the 4th order Runge-Kutta method
- ▶ Large material budget: Energy loss (ionization: Bethe-Bloch, bremsstrahlung: Bethe-Heitler); Multiple scattering (Gaussian approximation)

## Global track selection

- ▶ aim: remove clone and ghost tracks
- ▶ tracks are sorted by their quality, obtained by chi-square and track length
- ▶ Check for shared hits

## Tools

- ▶ TGeoManager
- ▶ Full magnetic field map

# Track reconstruction

## Discussion

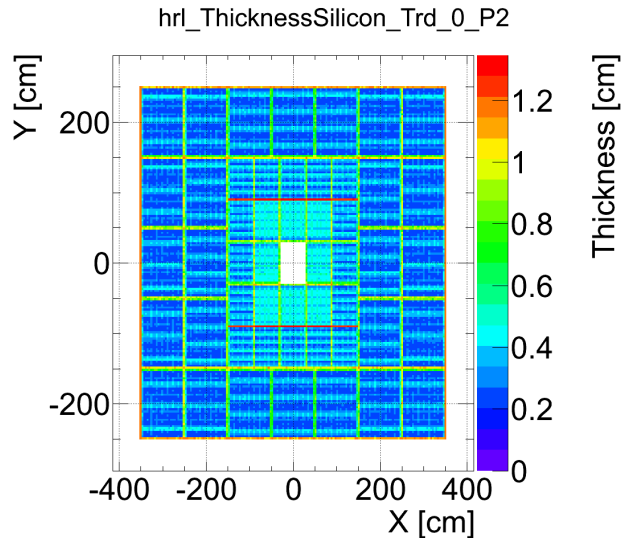

- ▶ **Disadvantage:**
  - ▶ Relatively slow calculation time
  - ▶ Hard to implement SIMD version
- ▶ **Advantage:**
  - ▶ General tracking algorithm. Can be used for different geometries and different experiment setups without modifications.
- ▶ **How to improve calculation time:**
  - ▶ Simplification of geometry -> fast access to material budget.
  - ▶ Approximation of magnetic field.

# Optimization of the tracking algorithm. Magnetic field approximation.

- ▶ Track propagation
- ▶ Two approaches:
  - ▶ OLD: polynomial approximation
    - ▶ bad quality for  $Z > 2\text{m}$  due to B-field fluctuations.
  - ▶ NEW: Field approximated as grid slice in  $(X, Y)$ 
    - ▶ High accuracy
    - ▶ Low memory consumption
    - ▶ It's fast
    - ▶ No SIMD access

# Optimization of the tracking algorithm. Geometry representation in tracking

Material approximation in silicon equivalent

## Detector geometry:

- stations: material + field + hits
- virtual stations: material + field

- Standard implementation of tracking uses full B-field map and TGeoManager and much better optimized for different geometry setups.
- For a better optimization one needs to optimize algorithm for a certain detector geometry.

# The CBM RICH detector

## RICH: electron identification by Cherenkov radiation

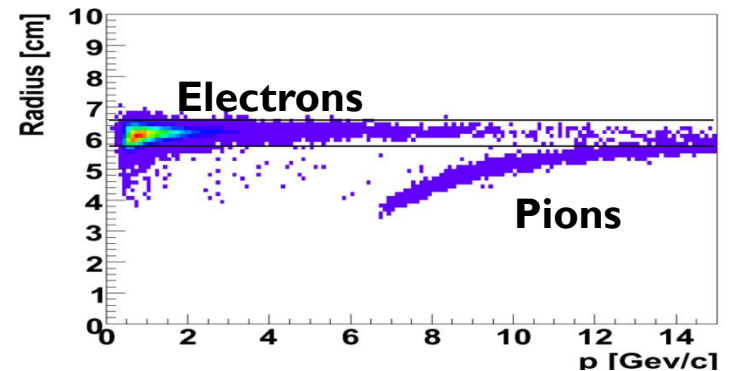

### RICH characteristics:

- ❑ **radiator:** CO<sub>2</sub> length 1.7 m;  $P_{th,\pi} = 4.65$  GeV/c
- ❑ **glass mirror of 6 mm thickness:**  
3m radius; 11.8 m<sup>2</sup> size
- ❑ **photodetector Hamamatsu H8500 MAPMT:**  
2.4 m<sup>2</sup> -> 55k channels

**Mean number of hits per electron ring is 22.**

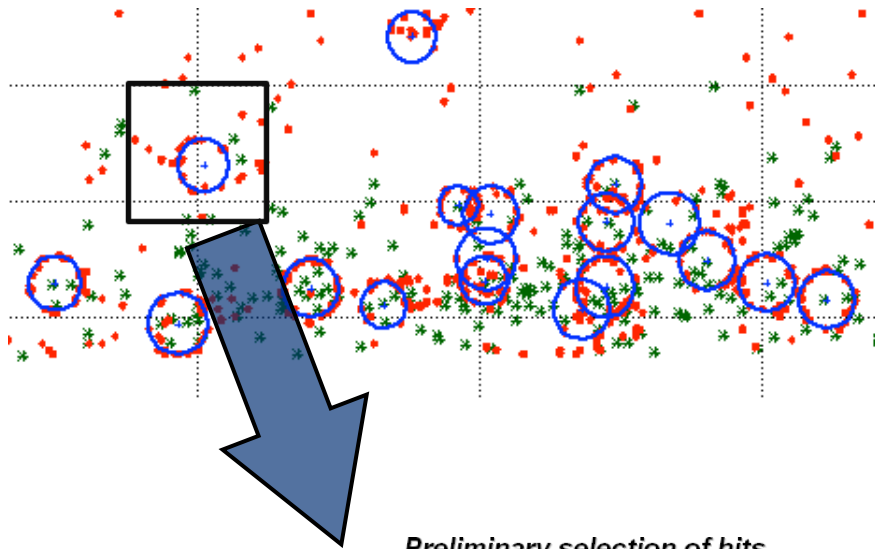

**RICH hits (blue), found rings (red), track projections (green).**

**Radius vs. momentum for reconstructed rings.**

# Hough Transform for the ring reconstruction

Detector space

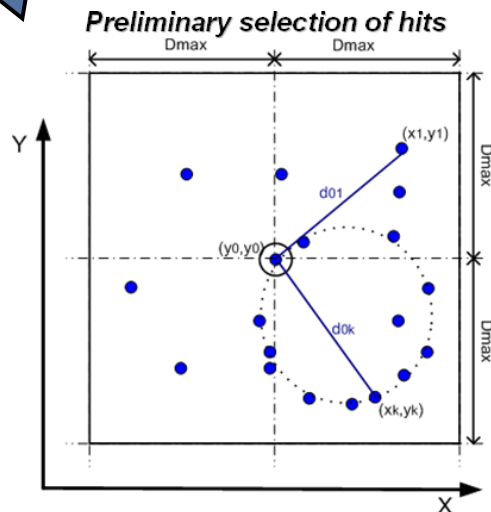

HT Space

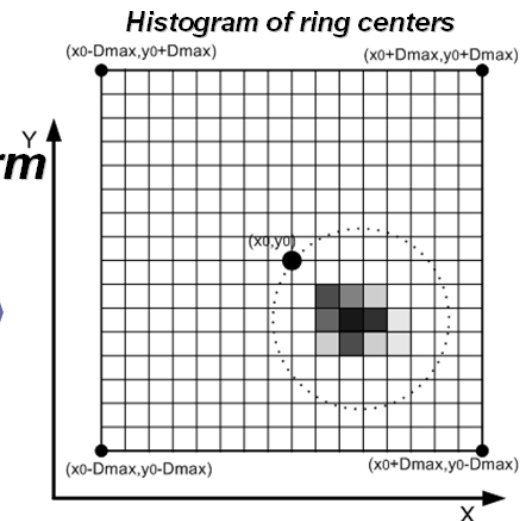

Hough Transform

**Hough Transform:**  
large combinatorics => slow  
**Localized Hough Transform:**  
much less combinatorics => fast

Hough Transform

# Reconstruction performance in RICH

**Simulation:** UrQMD events at 25 AGeV Au-Au collisions  
+ **omega meson  $\rightarrow e^+e^-$**  embedded in each event.

Algorithm	Time/ev [ms]
Initial	800
Fast	45

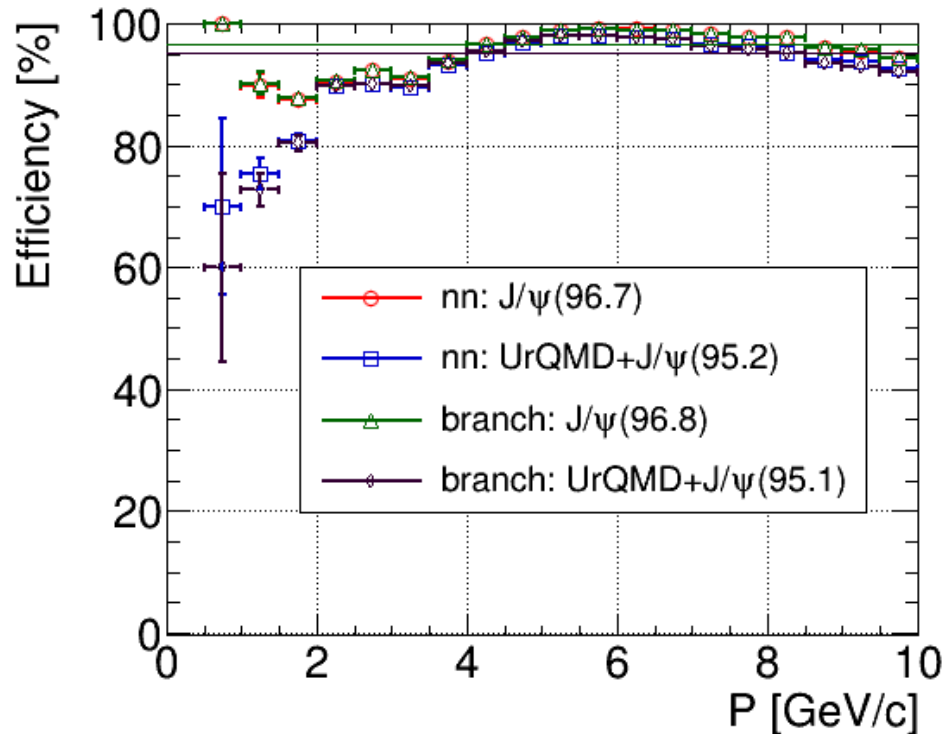

- ▶ Speedup factor 17.7.
- ▶ Reconstruction efficiency is more than 90%.

**RICH acceptance: rings with  $\geq 7$  hits. Ref:  $\geq 15$  hits.**

# Track reconstruction performance in MUCH

**MUCH acceptance: tracks with  $\geq 7$  hits.**

**Simulation: UrQMD events at 25 AGeV Au-Au collisions  
J/psi meson  $\rightarrow \mu^+\mu^-$**

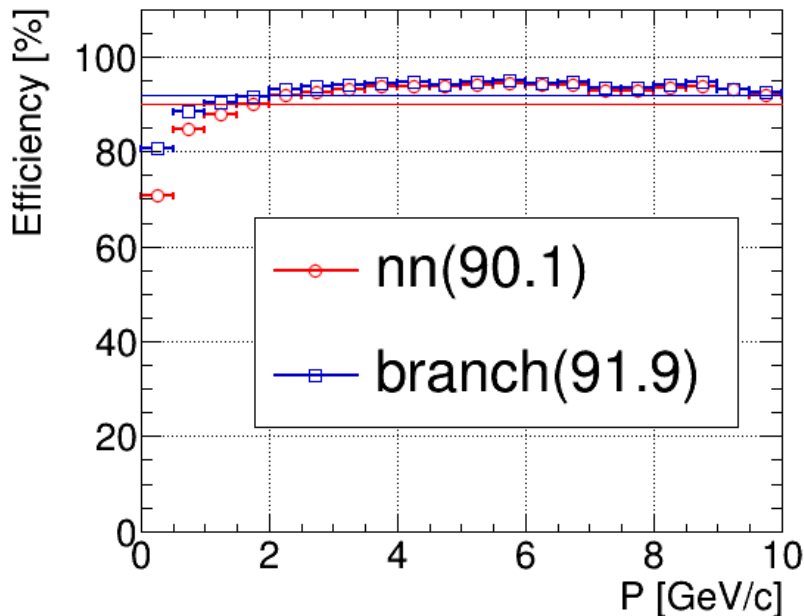

- ▶ Both tracking approaches show the same performance

# Track reconstruction performance in TRD

**TRD acceptance: TRD tracks with  $\geq 8$  hits.**

**Simulation: UrQMD at 25 AGeV Au-Au collisions + J/Psi  $\rightarrow e^+e^-$  embedded in each event.**

Algorithm	Time/ev [ms]
Branching std	2500
Nearest neighbor std	1300
Fast nearest neighbor	90

Preliminary!  
Speedup factor 14.

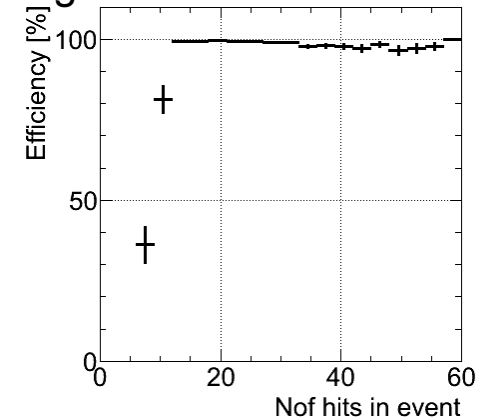

- ▶ Branching tracking performance is slightly better in comparison to nearest neighbor approach, however NN algorithm is faster and easier to implement.

# RICH prototype

RICH box

Ring reconstruction efficiency

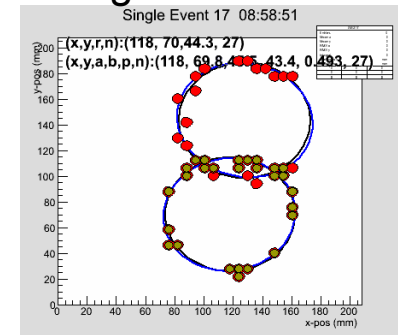

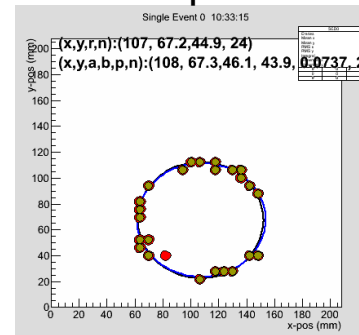

Photodetectors

Mirrors

Example of detected rings in RICH

- ▶ Full-size RICH prototype was successfully tested in CERN in 2011 and 2012.
- ▶ Developed algorithms were used for event reconstruction for RICH prototype.

# Summary

- ▶ Event reconstruction algorithms in the RICH, TRD and MUCH detectors were presented.
- ▶ Although standard reconstruction algorithms are slower, but they are more general and do not depend strongly on geometry. Development of fast algorithms leads to implementation which strongly depends on a certain geometry.
- ▶ Ring reconstruction algorithm were used for data analysis for the CBM-RICH prototype.
