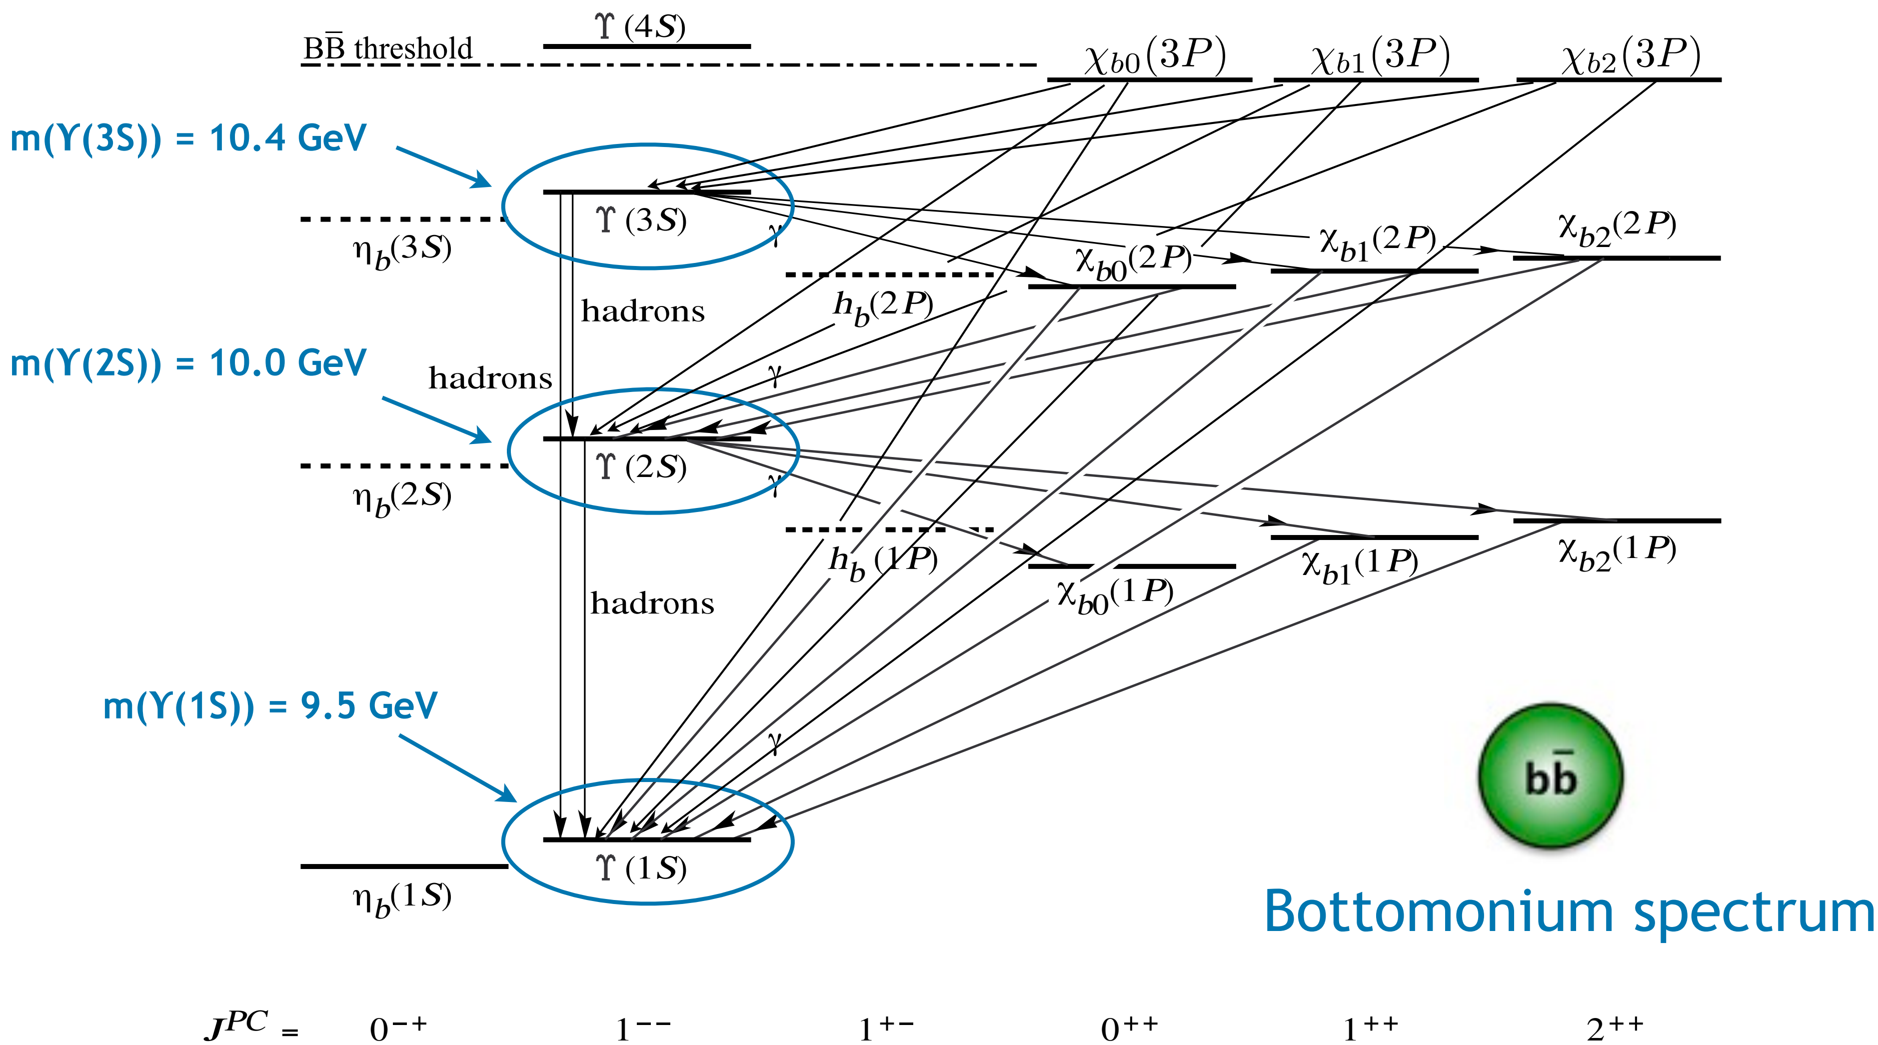
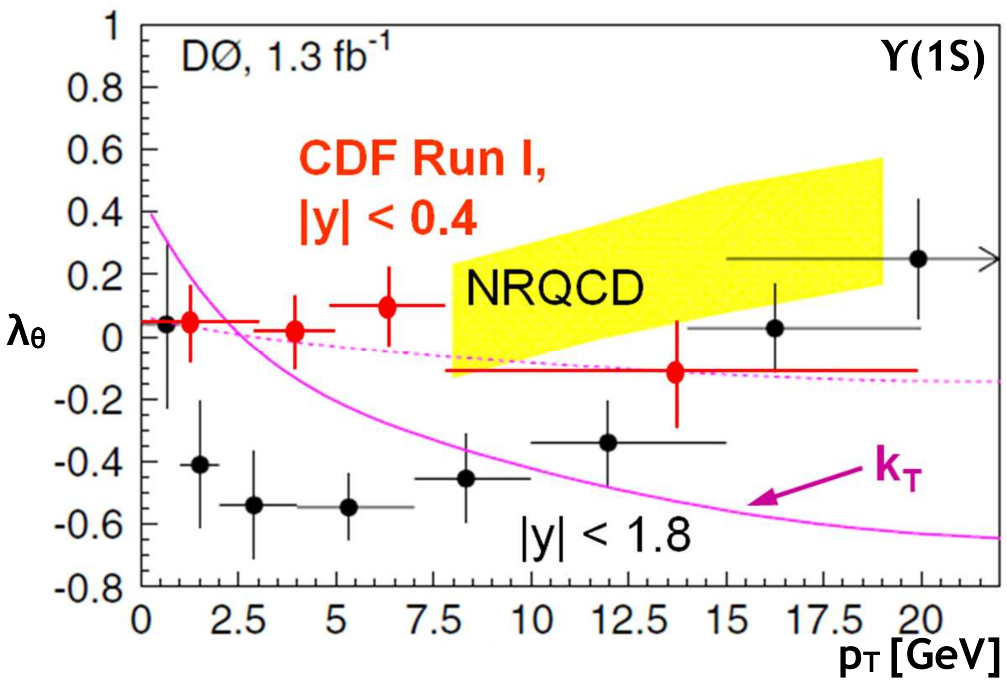
Introduction



Bottomonium spectrum

Motivation

- Even after decades of theoretical and experimental research, quarkonium production is still not well understood
- Quarkonium polarization is sensitive to the production mechanism and therefore important to the theoretical understanding



NRQCD factorization
Braaten & Lee, Phys. Rev. D63, 071501(R) (2001)

DØ
DØ Collaboration, Phys. Rev. Letters 101, 182004 (2008)

CDF Run I
CDF Collaboration, Phys. Rev. Lett. 88, 161802 (2002)

k_T factorization
Baranov & Zotov, JETP Lett. 86, 435 (2007)

Quarkonium Polarization

- Polarization is measured through the average angular decay distribution – for vector particles most generally written as

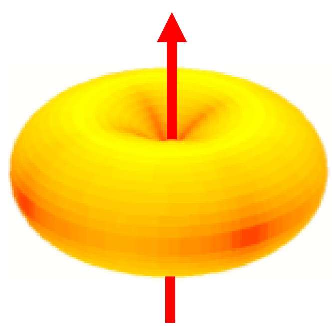
$$\frac{dN}{d\cos\theta d\phi} \propto 1 + \lambda_\theta \cos^2\theta + \lambda_\phi \sin^2\theta \cos 2\phi + \lambda_{\theta\phi} \sin 2\theta \cos\phi$$

where λ_θ, λ_Φ, $\lambda_{\theta\Phi}$ are the polarization parameters

- Two extreme angular decay distributions:

Longitudinal polarization
$J_z = 0$

$\lambda_\theta = -1$
$\lambda_\phi = 0$
$\lambda_{\theta\phi} = 0$

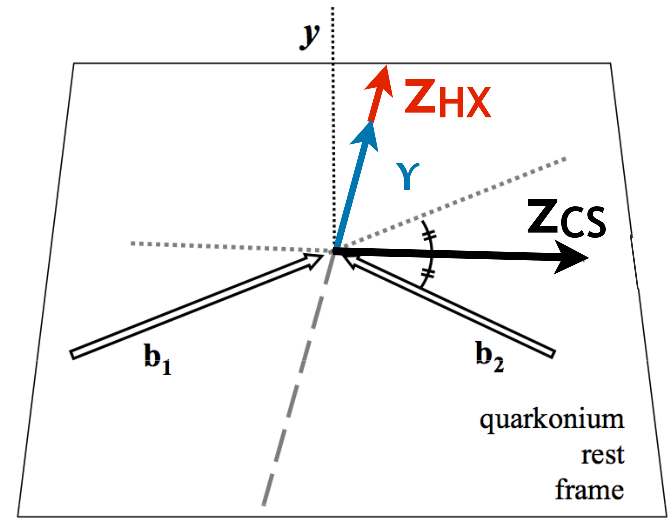


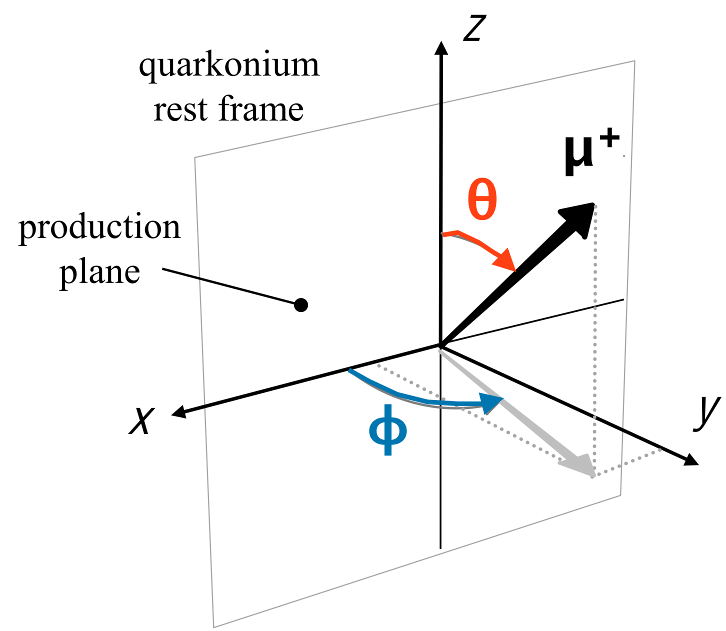
Transverse polarization
$J_z = \pm 1$

$\lambda_\theta = +1$
$\lambda_\phi = 0$
$\lambda_{\theta\phi} = 0$

Definitions

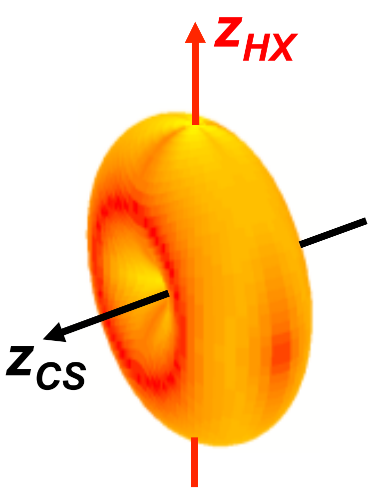
- Angular decay distribution measured with respect to a certain reference frame:
  - center-of-mass helicity HX (polar axis z_{HX} ≈ direction of quarkonium momentum)
  - Collins-Soper CS (z_{CS} ≈ direction of relative velocity of colliding particles)
  - perpendicular helicity PX ($z_{PX} \perp z_{CS}$)
- Usage of the dimuon decay channel $\Upsilon(nS) \rightarrow \mu^+\mu^-$





Need to Measure Full Angular Distribution

- Only λ_θ in one reference frame was measured in the past
- The full angular decay distribution (three polarization parameters) should be measured: Two very different physical cases are indistinguishable if only λ_θ is measured.
- Observed polarization depends on the frame



$$\lambda_\theta = +1 \quad \lambda_\phi = -1$$

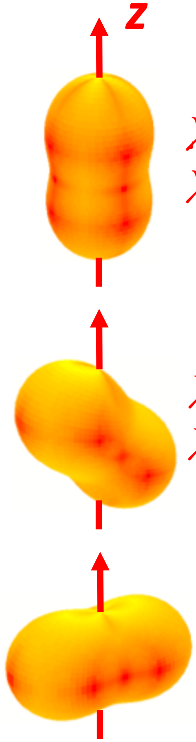
$$\lambda_\theta = -1 \quad \lambda_\phi = 0$$

$$\lambda_\theta = +1 \quad \lambda_\phi = 0$$

Frame Independent Parameter

- Define frame invariant parameters such as $\tilde{\lambda}$ from the angular decay distribution of a given frame

$$\tilde{\lambda} = \frac{\lambda_\theta + 3\lambda_\phi}{1 - \lambda_\phi}$$



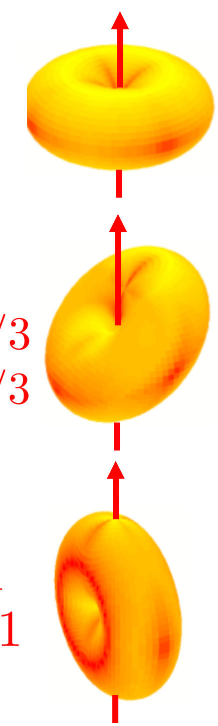
$\lambda_\theta = +1$, $\lambda_\phi = 0$

$\lambda_\theta = +1/5$, $\lambda_\phi = +1/5$

$\lambda_\theta = -1/3$, $\lambda_\phi = -1/3$

$\tilde{\lambda} = +1$

$\tilde{\lambda} = -1$



$\lambda_\theta = -1$, $\lambda_\phi = 0$

$\lambda_\theta = -1/3$, $\lambda_\phi = +1/3$

$\lambda_\theta = +1$, $\lambda_\phi = -1$

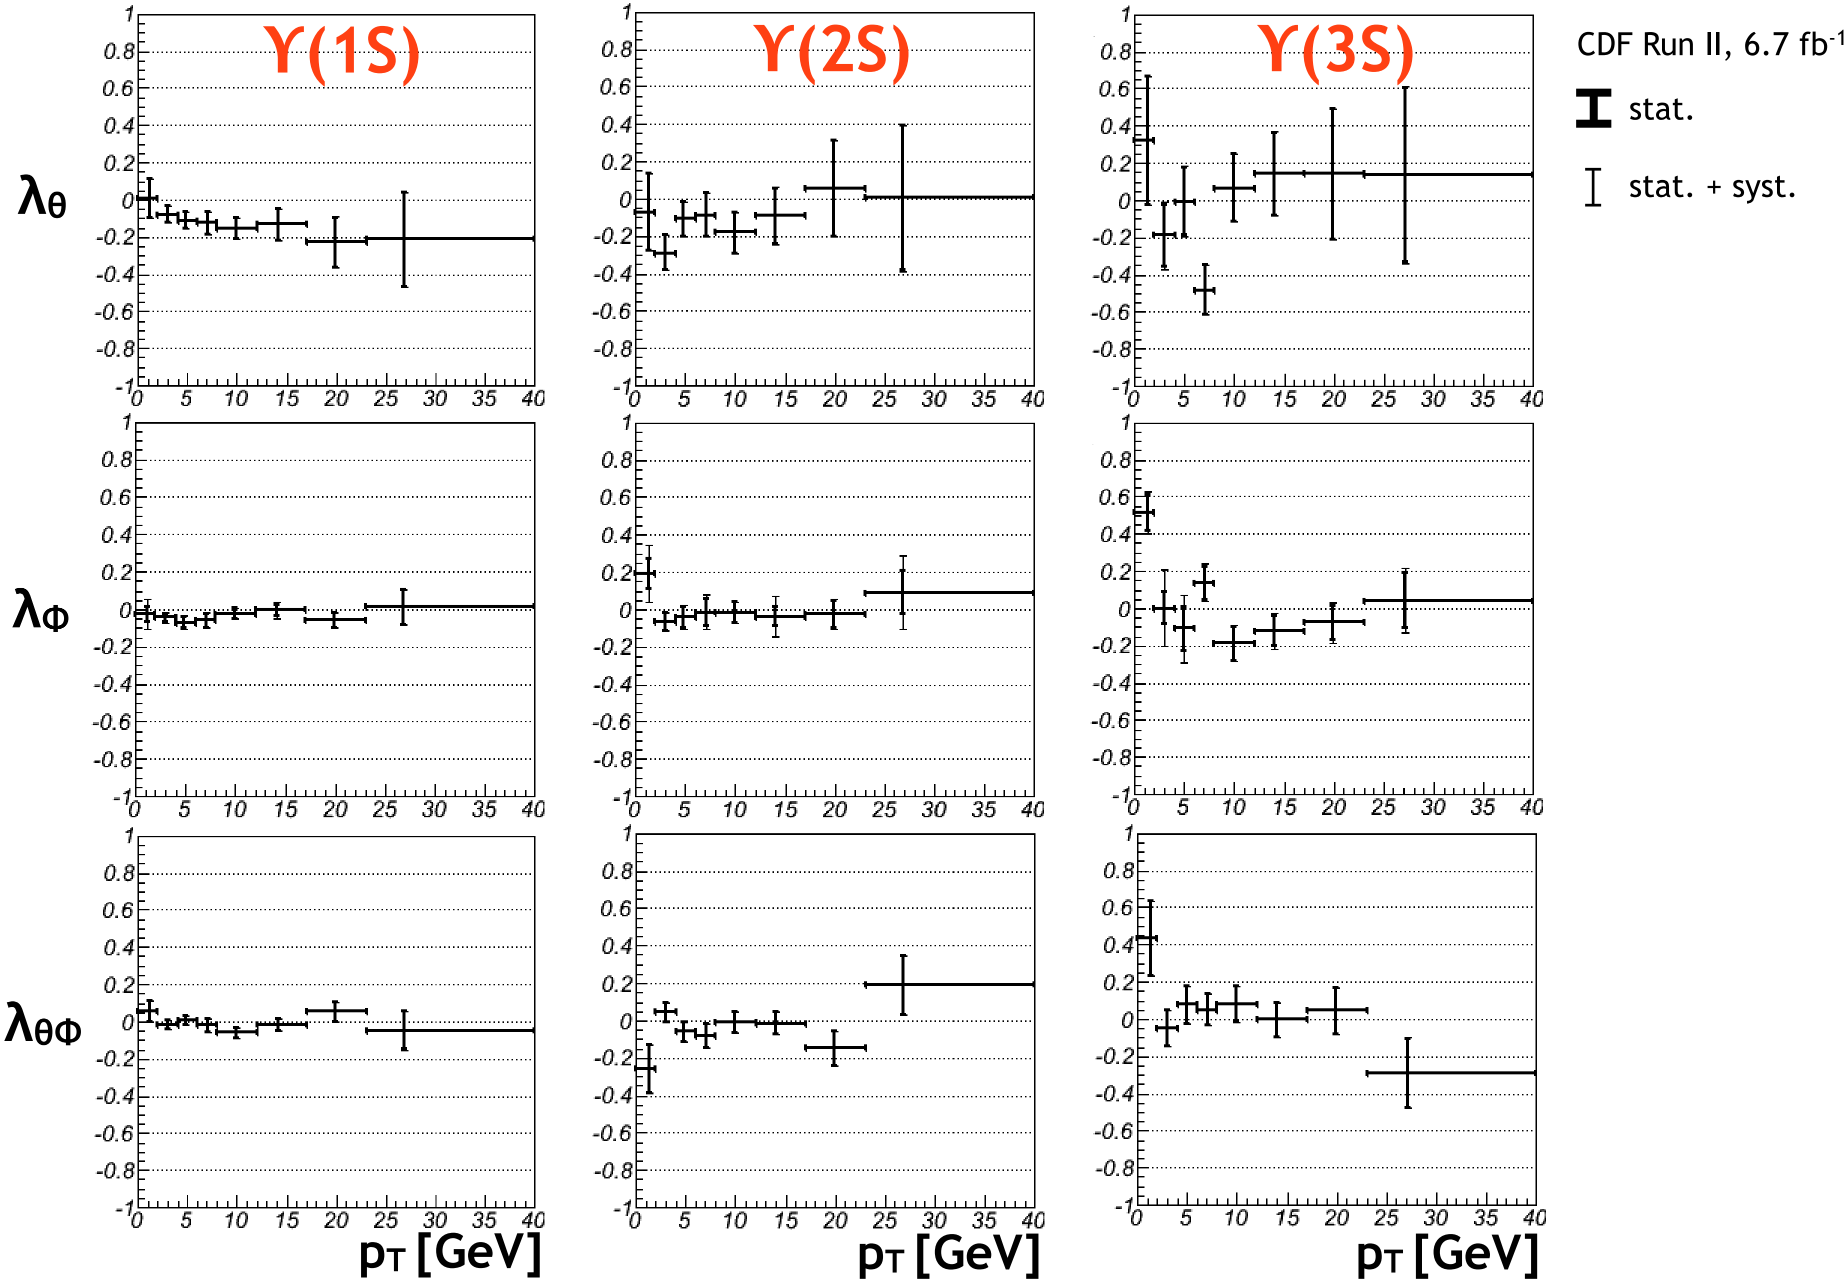
CDF Run II Υ(nS) Polarization Analysis

- Previous results only measured λ_θ in the HX frame
- In this analysis, λ_θ, λ_ϕ and $\lambda_{\theta\phi}$ are determined simultaneously in two different reference frames (CS, HX) for Υ(1S), Υ(2S) and Υ(3S) mesons – self-consistency of the results is tested with $\tilde{\lambda}$
- A dimuon sample collected in $p\bar{p}$ collisions at $\sqrt{s}$ = 1.96 TeV, corresponding to a total integrated luminosity of 6.7 fb^{-1}, is used
- Estimated number of signal events in the kinematic phase space under consideration (p_T < 40 GeV, $|y|$ < 0.6):

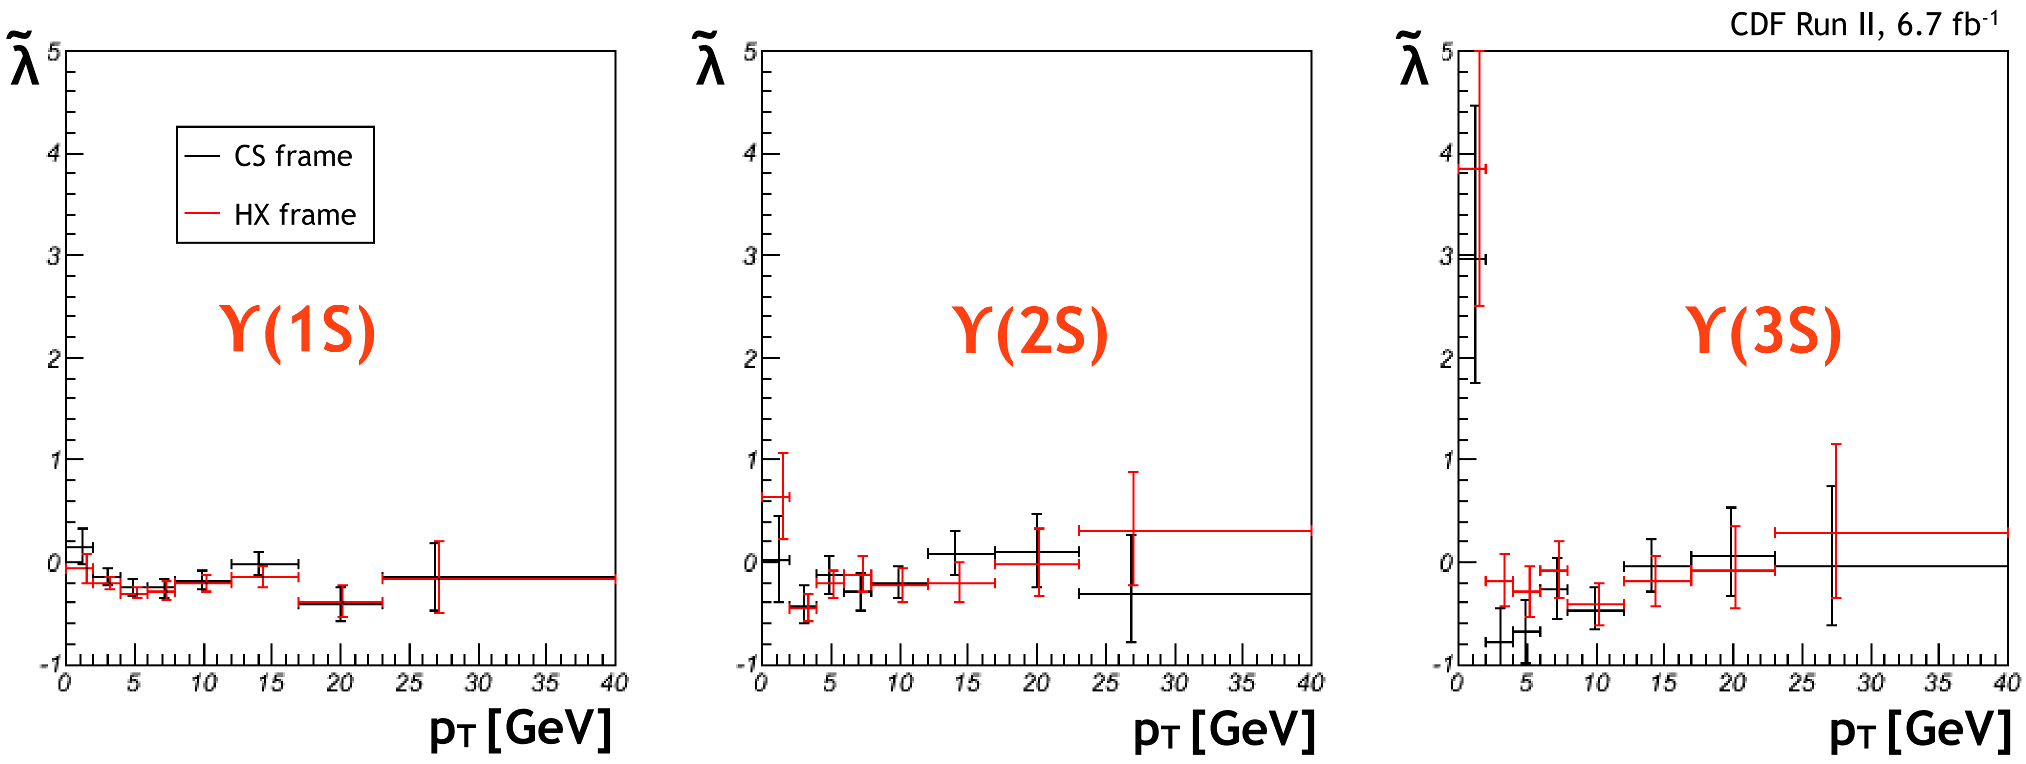
Υ(1S)	Υ(2S)	Υ(3S)
550k	150k	76k

Details in PRL 108, 151802 (2012): "Measurements of the Angular Distributions of Muons from Υ Decays in $p\bar{p}$ Collisions at $\sqrt{s}$=1.96 TeV"

Υ(nS) Polarization in the HX Frame, |y| < 0.6



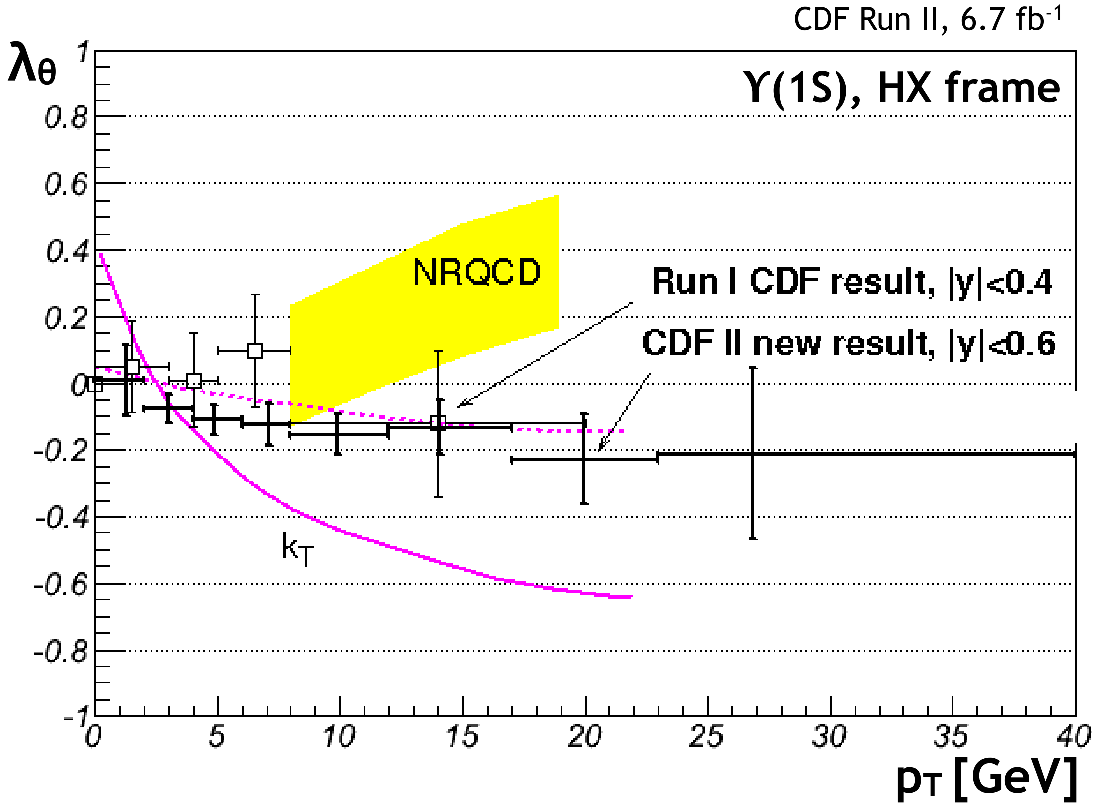
Frame Invariant Parameter $\tilde{\lambda}$



- Results of the two reference frames are consistent
- No evidence of strong polarization over a wide range of p_T

Comparison to Previous CDF Result

- New CDF Run II result agrees with the previous CDF Run I result



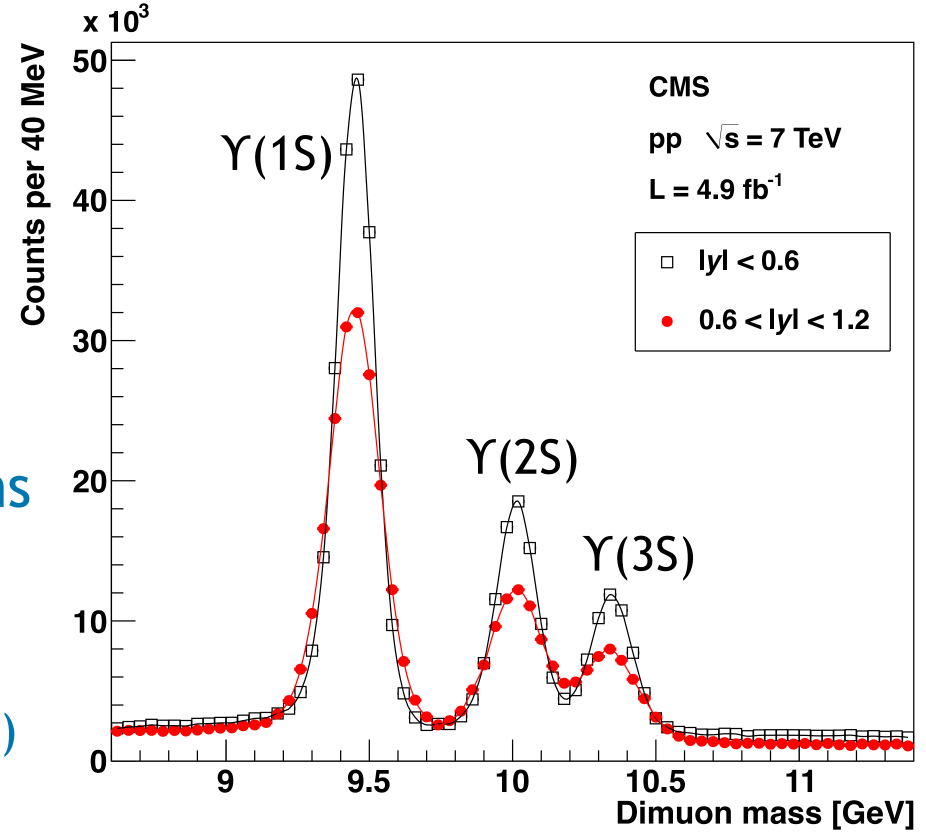
CMS Υ(nS) Polarization Analysis

- λ_θ, λ_ϕ, $\lambda_{\theta\phi}$ and $\tilde{\lambda}$ are measured in three different reference frames (PX, CS, HX) for Υ(1S), Υ(2S) and Υ(3S) mesons
- Analysis based on dimuon sample collected in pp collisions in 2011 at $\sqrt{s}$ = 7 TeV, corresponding to a total integrated luminosity of 4.9 fb^{-1}
- Estimated number of signal events in the kinematic phase space under consideration (p_T > 10 GeV, |y| < 1.2):

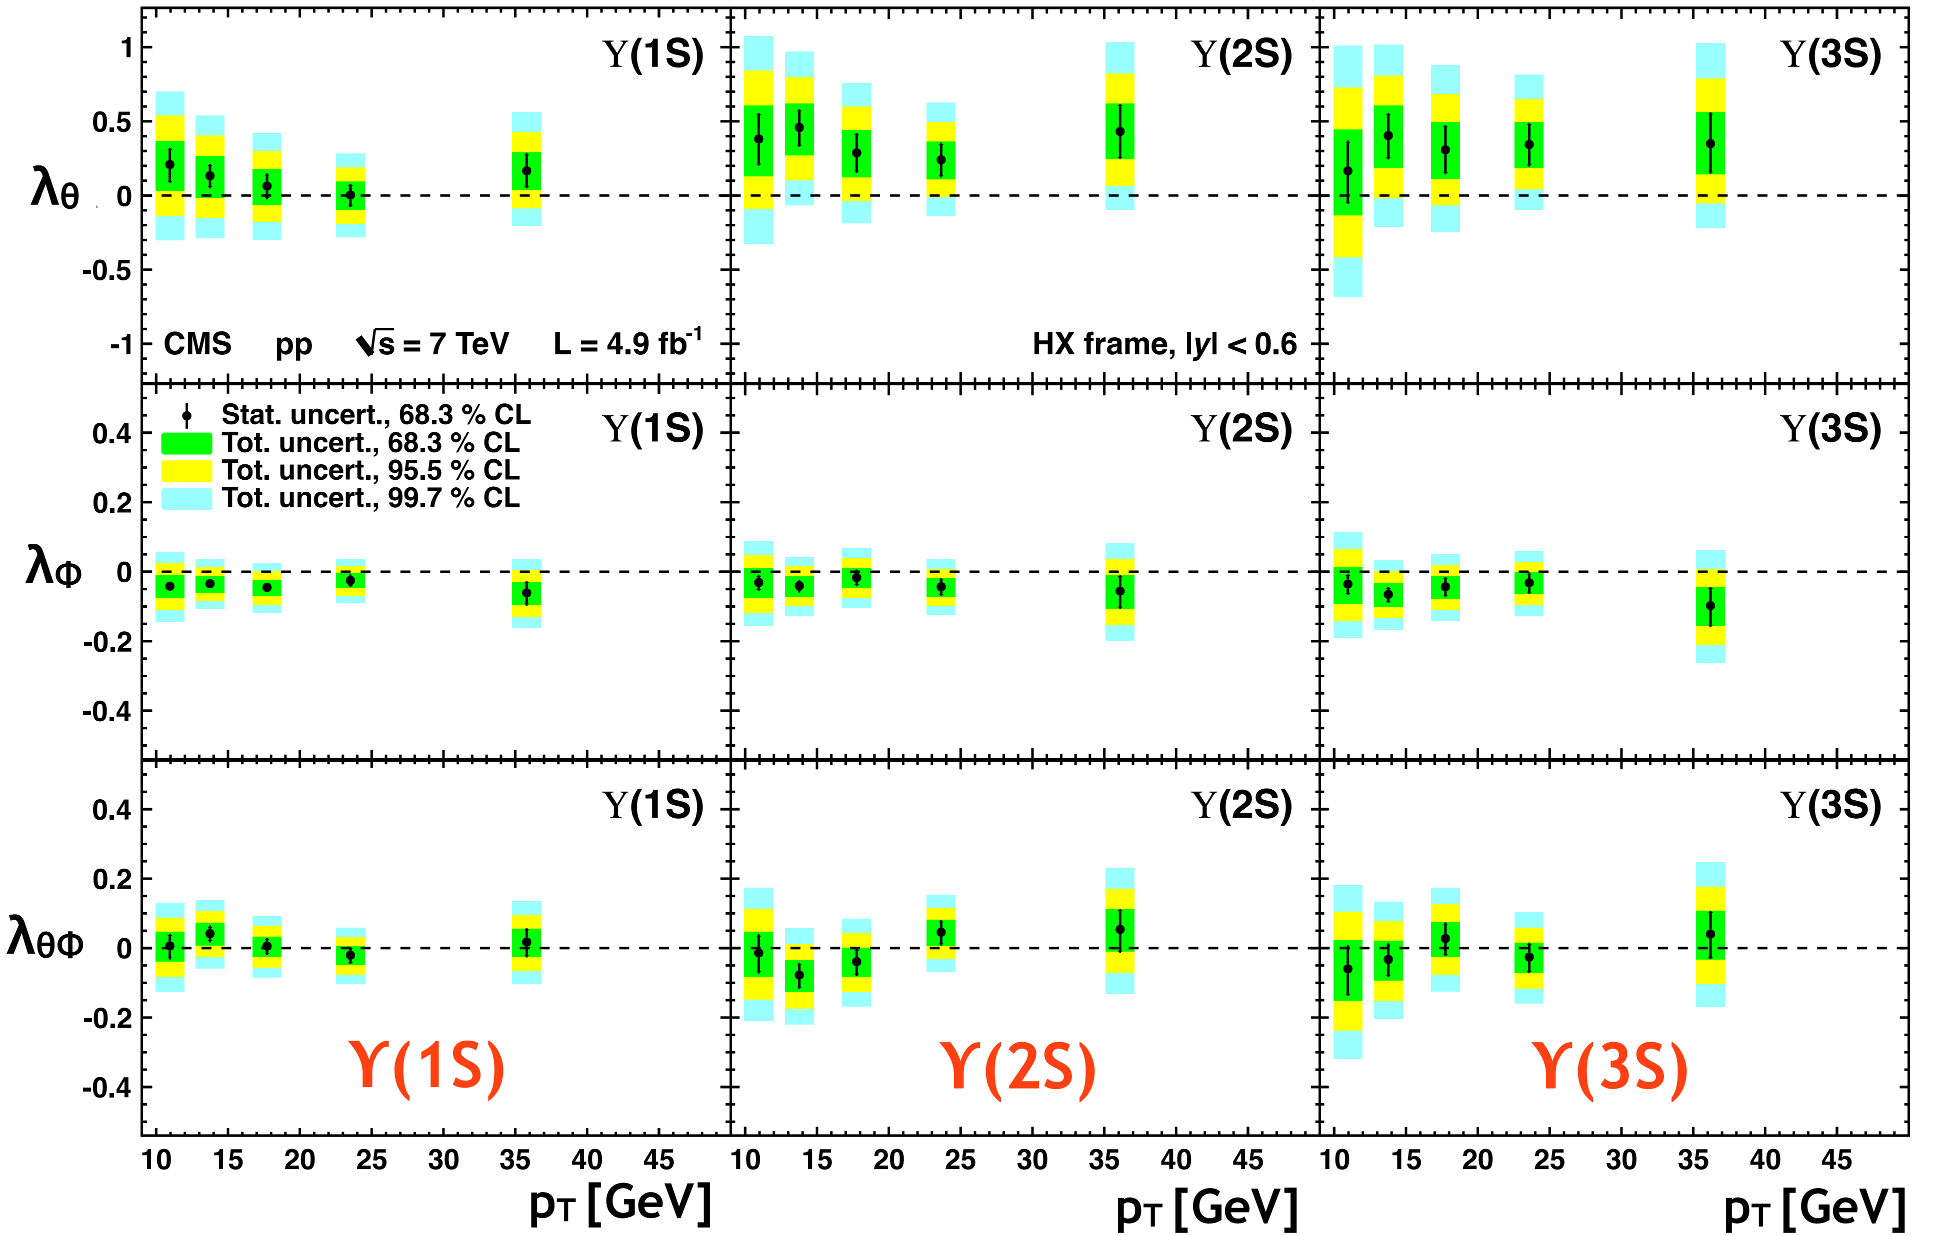
Υ(1S)	Υ(2S)	Υ(3S)
252k	94k	58k

- Analysis performed independently in five transverse momentum p_T bins for two dimuon rapidity |y| cells

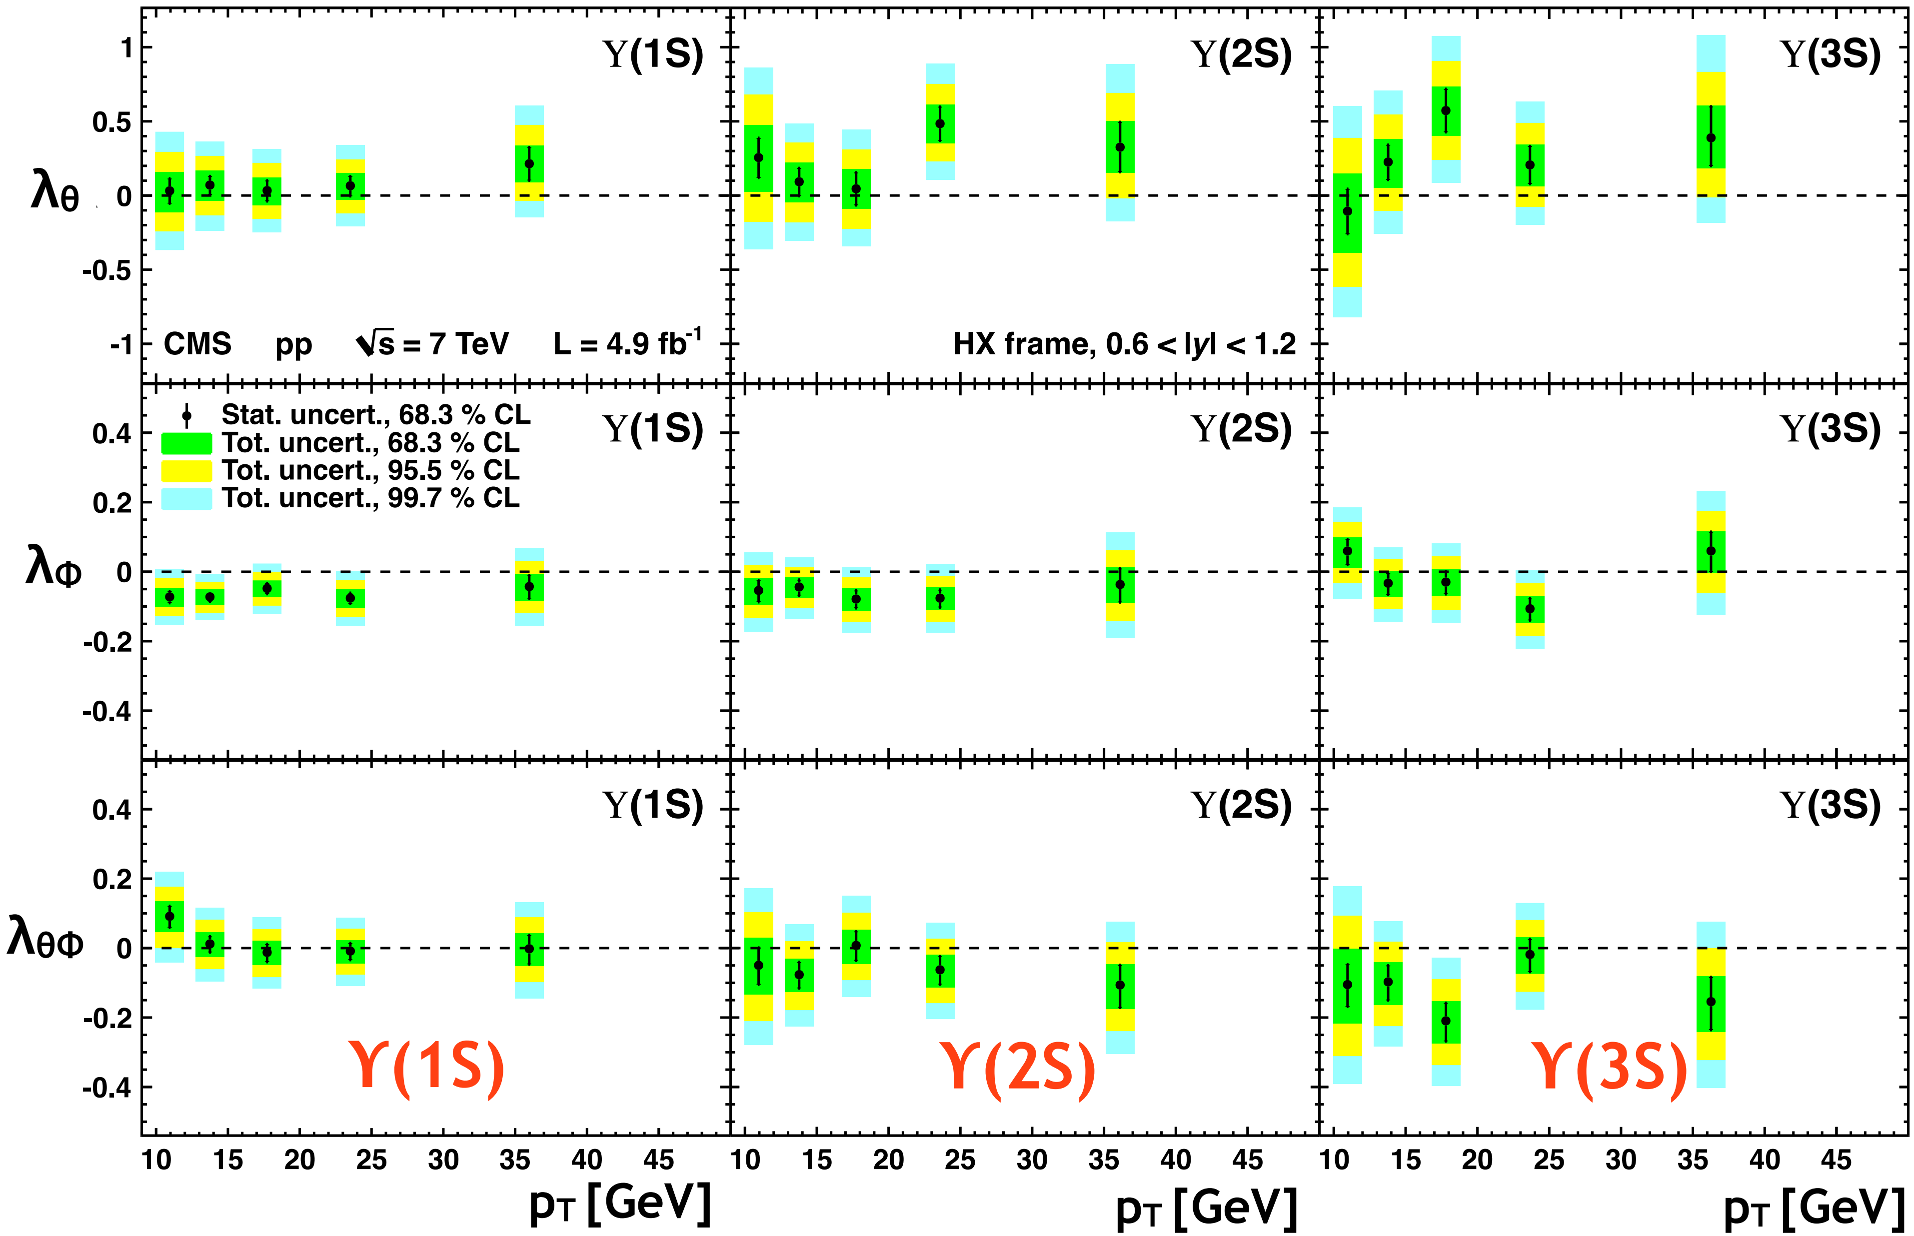
Details in PRL 110, 081802 (2013):
"Measurement of the Υ(1S), Υ(2S) and Υ(3S) polarizations in pp collisions at $\sqrt{s}$ = 7 TeV"



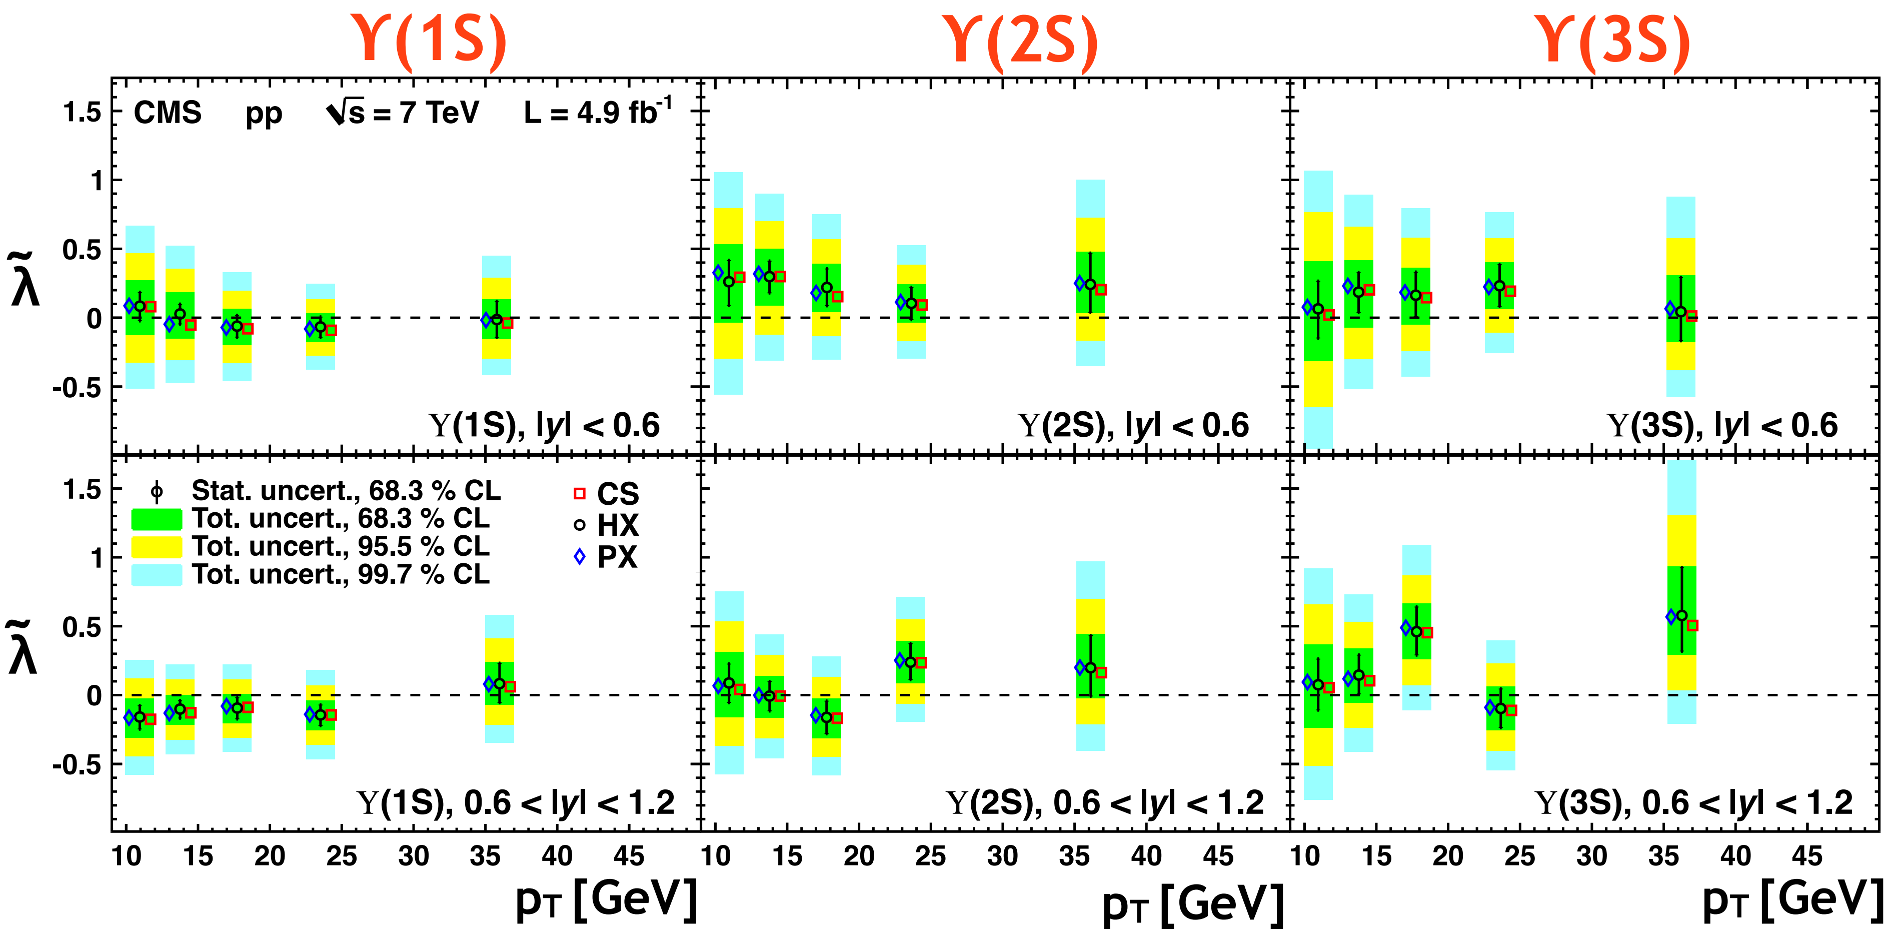
Υ(nS) Polarization in the HX Frame, |y| < 0.6



Υ(nS) Polarization in the HX Frame, 0.6 < |y| < 1.2

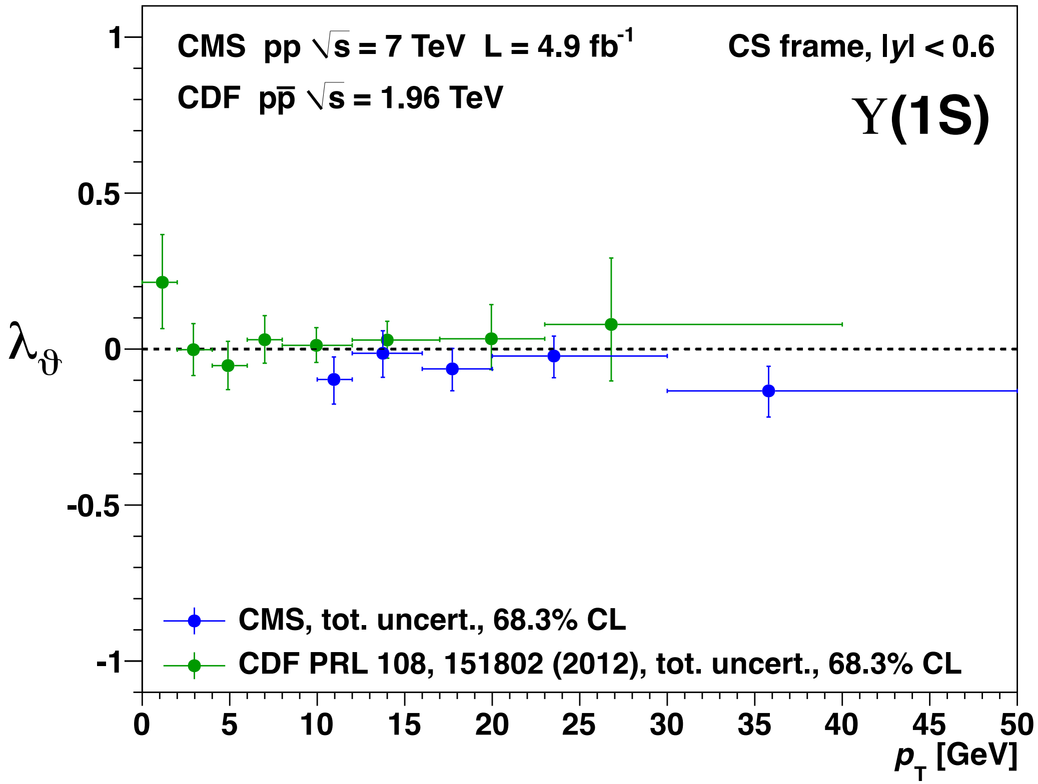


Frame Invariant Parameter $\tilde{\lambda}$



- Results of all three reference frames are consistent
- No evidence of unaccounted systematic uncertainties

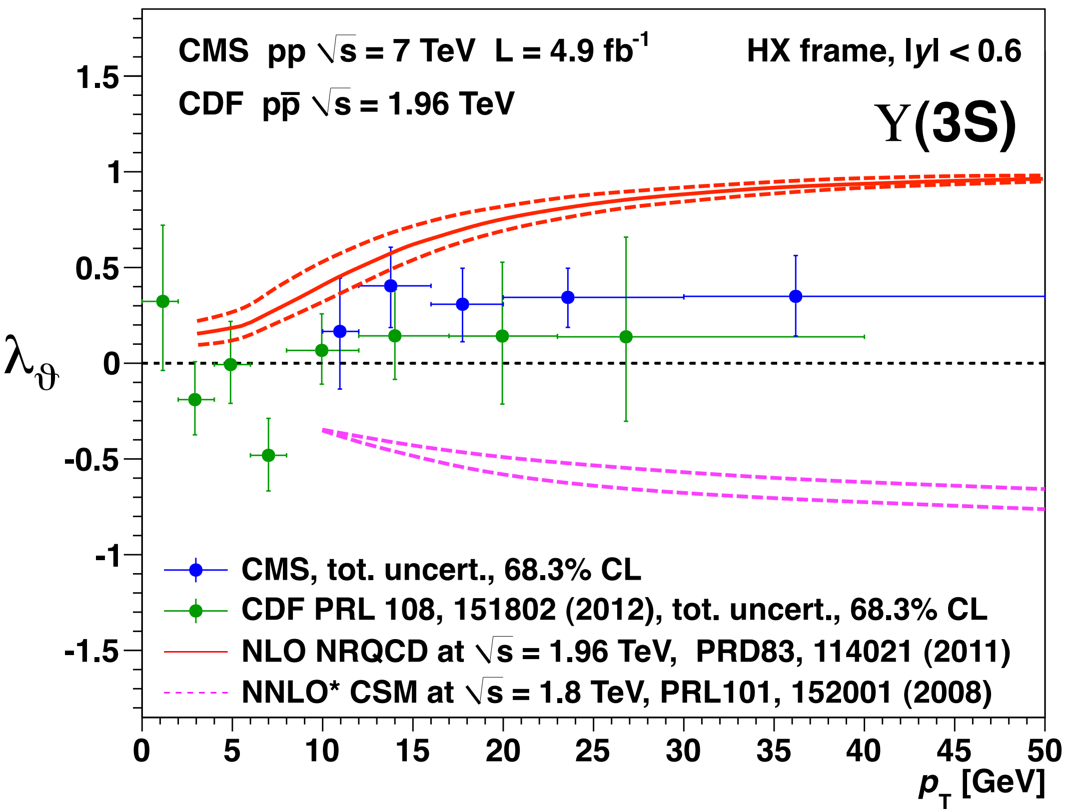
CDF vs CMS



- Results from CDF and CMS are consistent
- CMS extends the measurements beyond the p_T and rapidity ranges probed by CDF
  CDF: $p_T < 40$ GeV, $|y| < 0.6$
  CMS: $10 < p_T < 50$ GeV, $|y| < 1.2$
- Measurements do not show strong polarizations: puzzling!

Comparison to Theory

- $\Upsilon(1S)$ suffers from large χ_b feed-down contribution, with unknown polarization
- $\Upsilon(3S)$ polarization calculated more reliably
- Theory predictions do not agree with experimental results



Summary and Conclusions

- CDF as well as CMS measured the polarization of ϒ(1S), ϒ(2S) and ϒ(3S) mesons
- Three frame dependent anisotropy parameters λ_θ, λ_Φ, $\lambda_{\theta\Phi}$ and the frame invariant parameter $\tilde{\lambda}$ have been measured: CDF determined these parameters in two reference frames (CS, HX) while CMS obtained results in three different frames (CS, HX, PX)
- CMS results ($10 < p_T < 50$ GeV, $|y| < 1.2$) extended the measurements beyond the p_T and rapidity ranges probed by CDF ($p_T < 40$ GeV, $|y| < 0.6$)
- No evidence of strong longitudinal or transverse polarizations has been observed

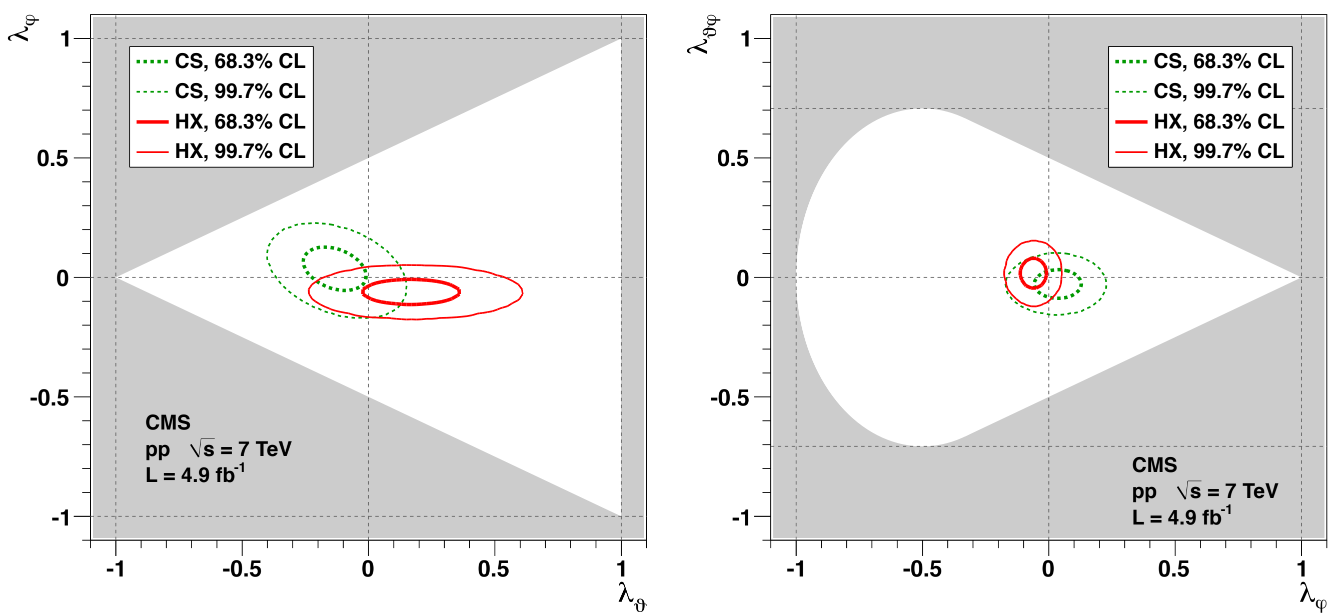
Obtaining Polarization Parameters

Full and direct calculation of the Posterior Probability Distribution (PPD) of the polarization parameters λ_θ, λ_Φ, $\lambda_{\theta\Phi}$

1. Events distributed as in the background model are subtracted from the data sample
2. Definition of the PPD from the remaining signal-like events
3. Numerical results and graphical representations are determined from 1D and 2D projections of the PPD



Υ(1S)
$|y| < 0.6$
$30 < p_T < 50$ GeV

Definition of the PPD

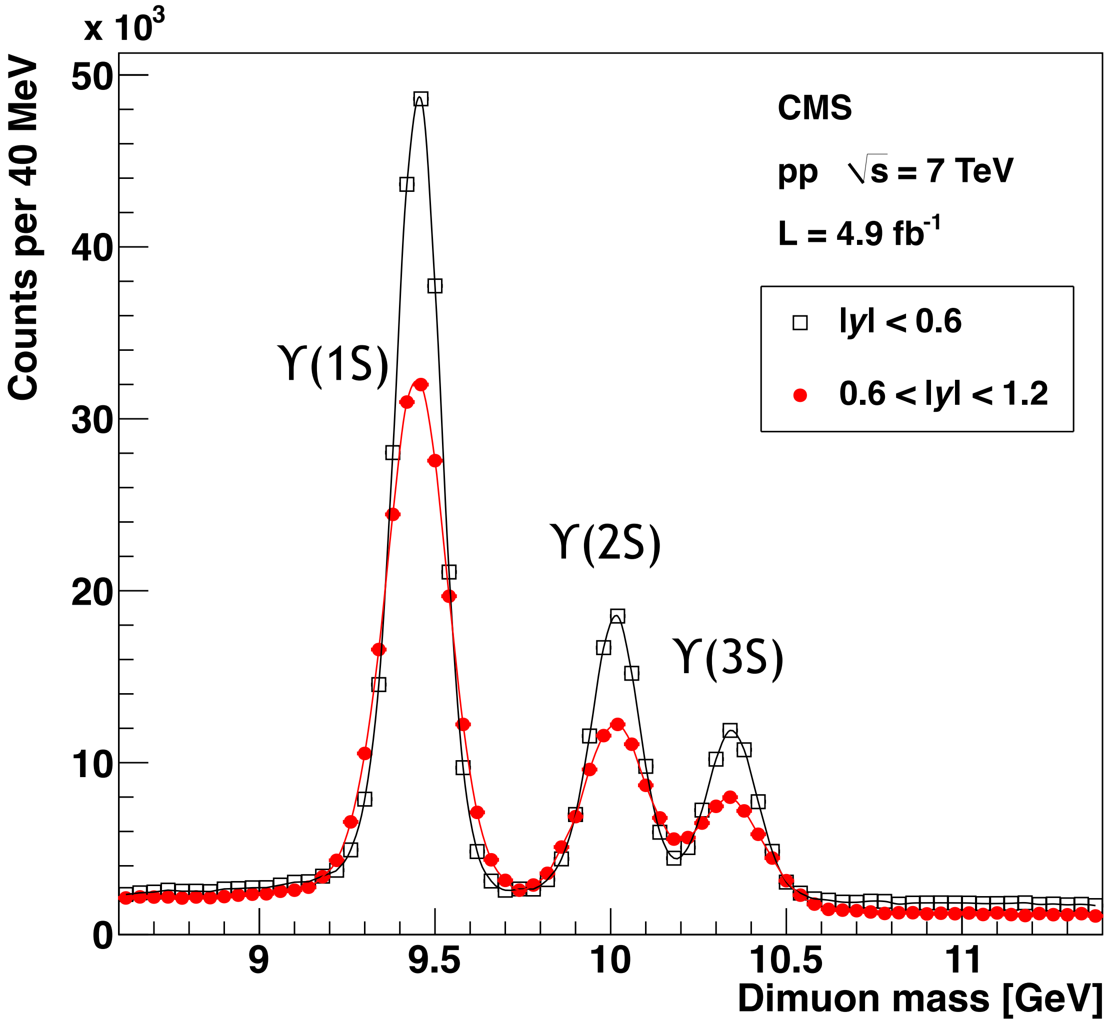
$$\mathcal{P}(\vec{\lambda}) \quad \propto \quad \prod_i \frac{1}{\mathcal{N}(\vec{\lambda})} \quad W(\cos\theta^{(i)}, \phi^{(i)} \mid \vec{\lambda}) \quad \varepsilon(\vec{p_1^{(i)}}\vec{p_2^{(i)}})$$

$\mathcal{N}$: normalization

W: general angular distribution

ε: dimuon efficiency as a function of the muon momenta

Background Subtraction

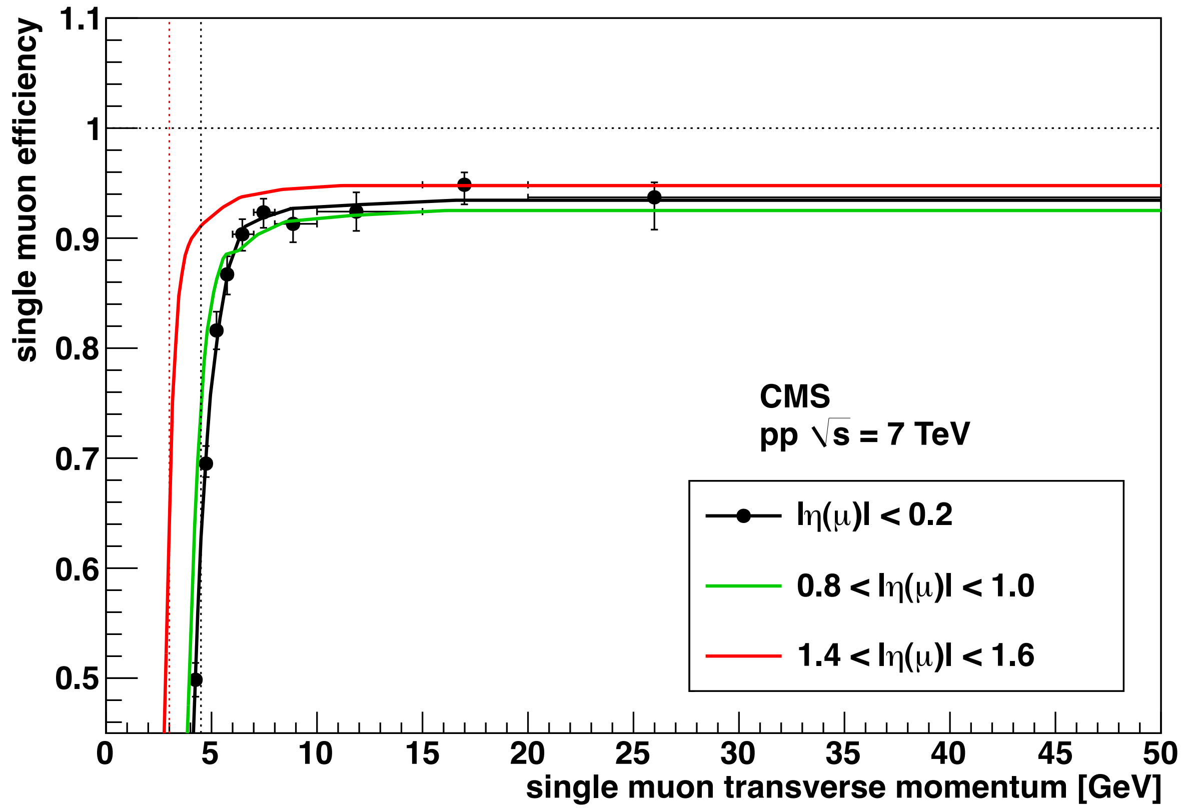


- Signal region is defined as ±1σ around mass peak
- Background fraction is determined by fits to the dimuon mass distribution
- Angular distribution of the background events are modeled as weighted sums of the distributions in the sidebands, left of ϒ(1S) and right of ϒ(3S) peak

- Event-by-event background subtraction of background-like events using a likelihood ratio criterion

Efficiencies

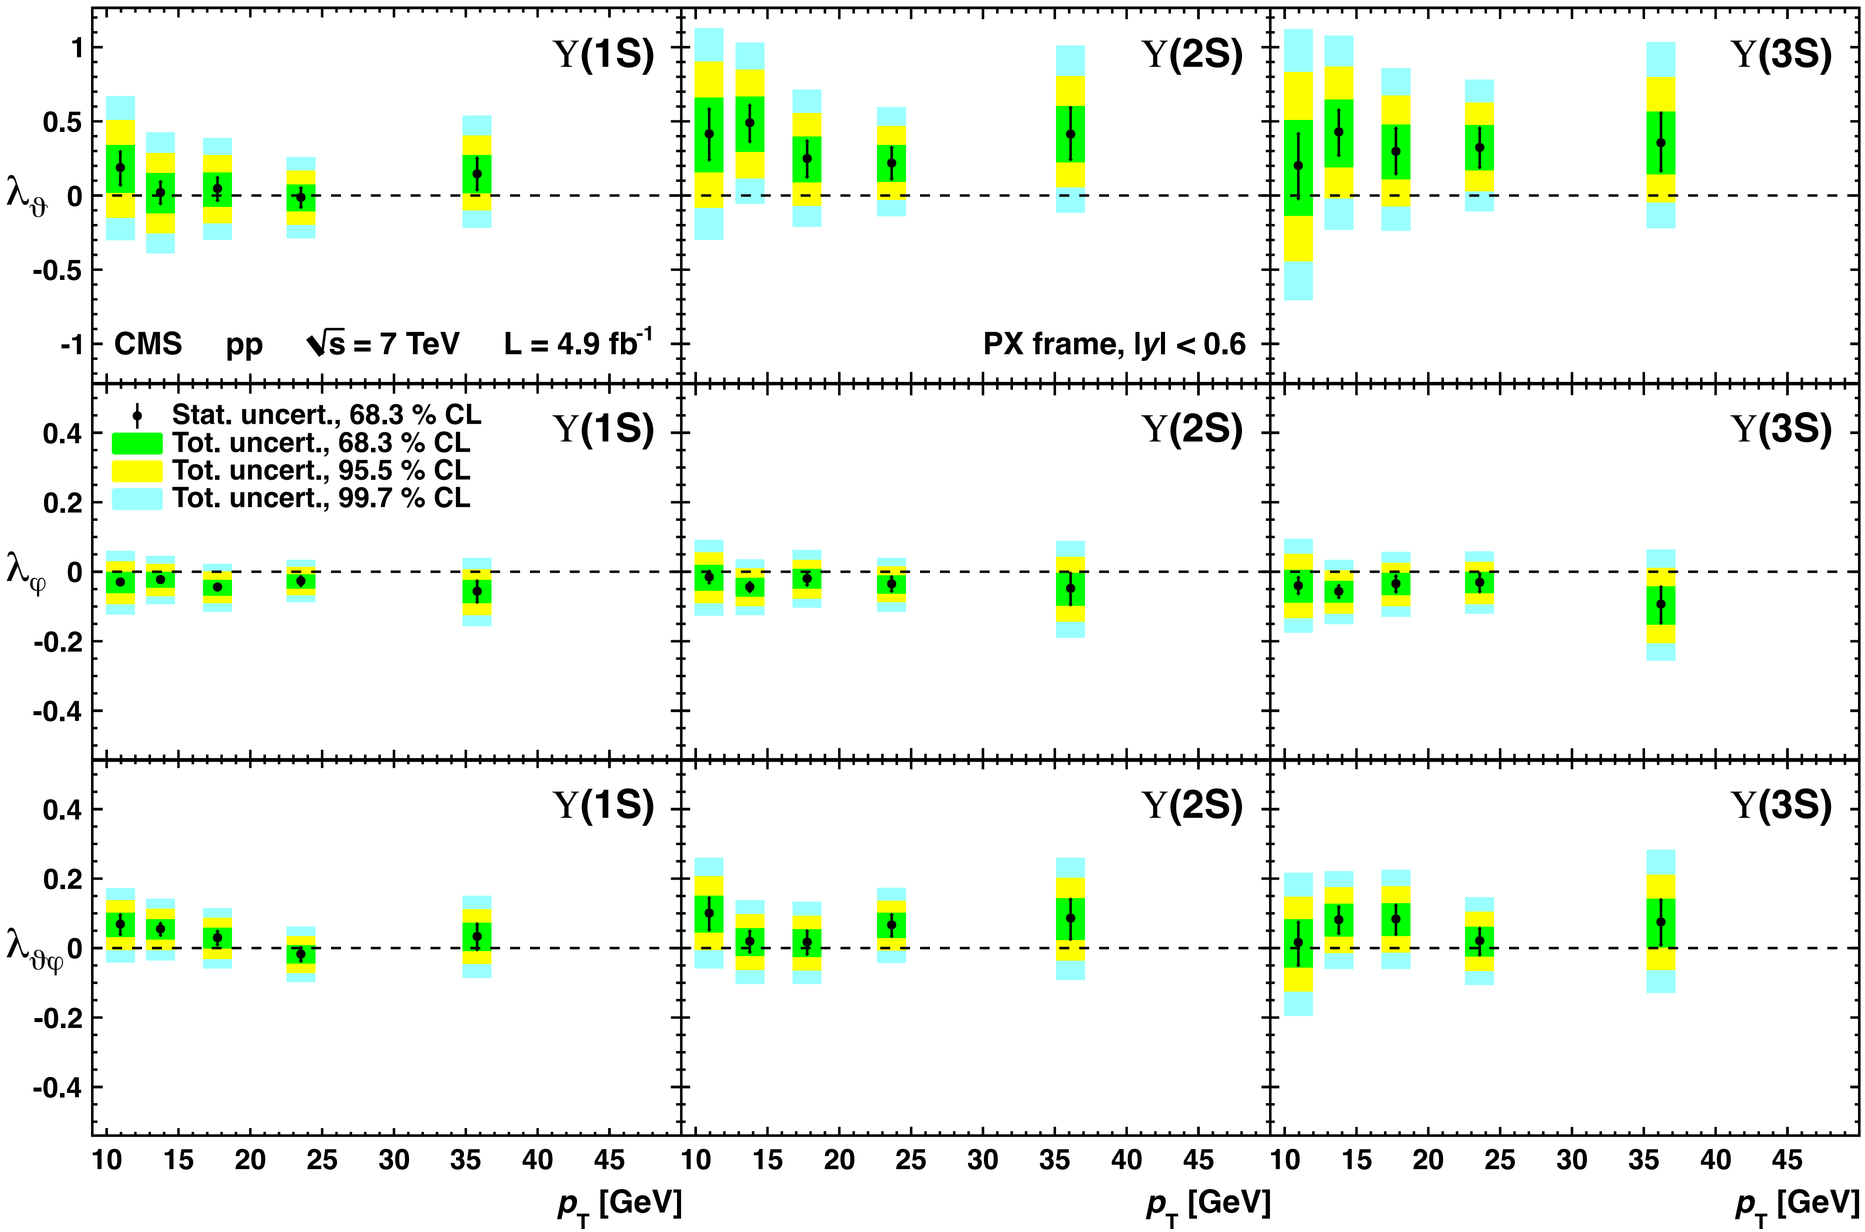
- Data-driven single muon efficiencies measured with the *Tag&Probe* method
- Precise knowledge of efficiencies needed to avoid introducing artificial polarization
- Dimuon efficiencies are calculated as the product of single muon efficiencies
- Correlations between muons are negligible as seen in detailed MC studies
- Efficiencies are accounted for on an event-by-event basis



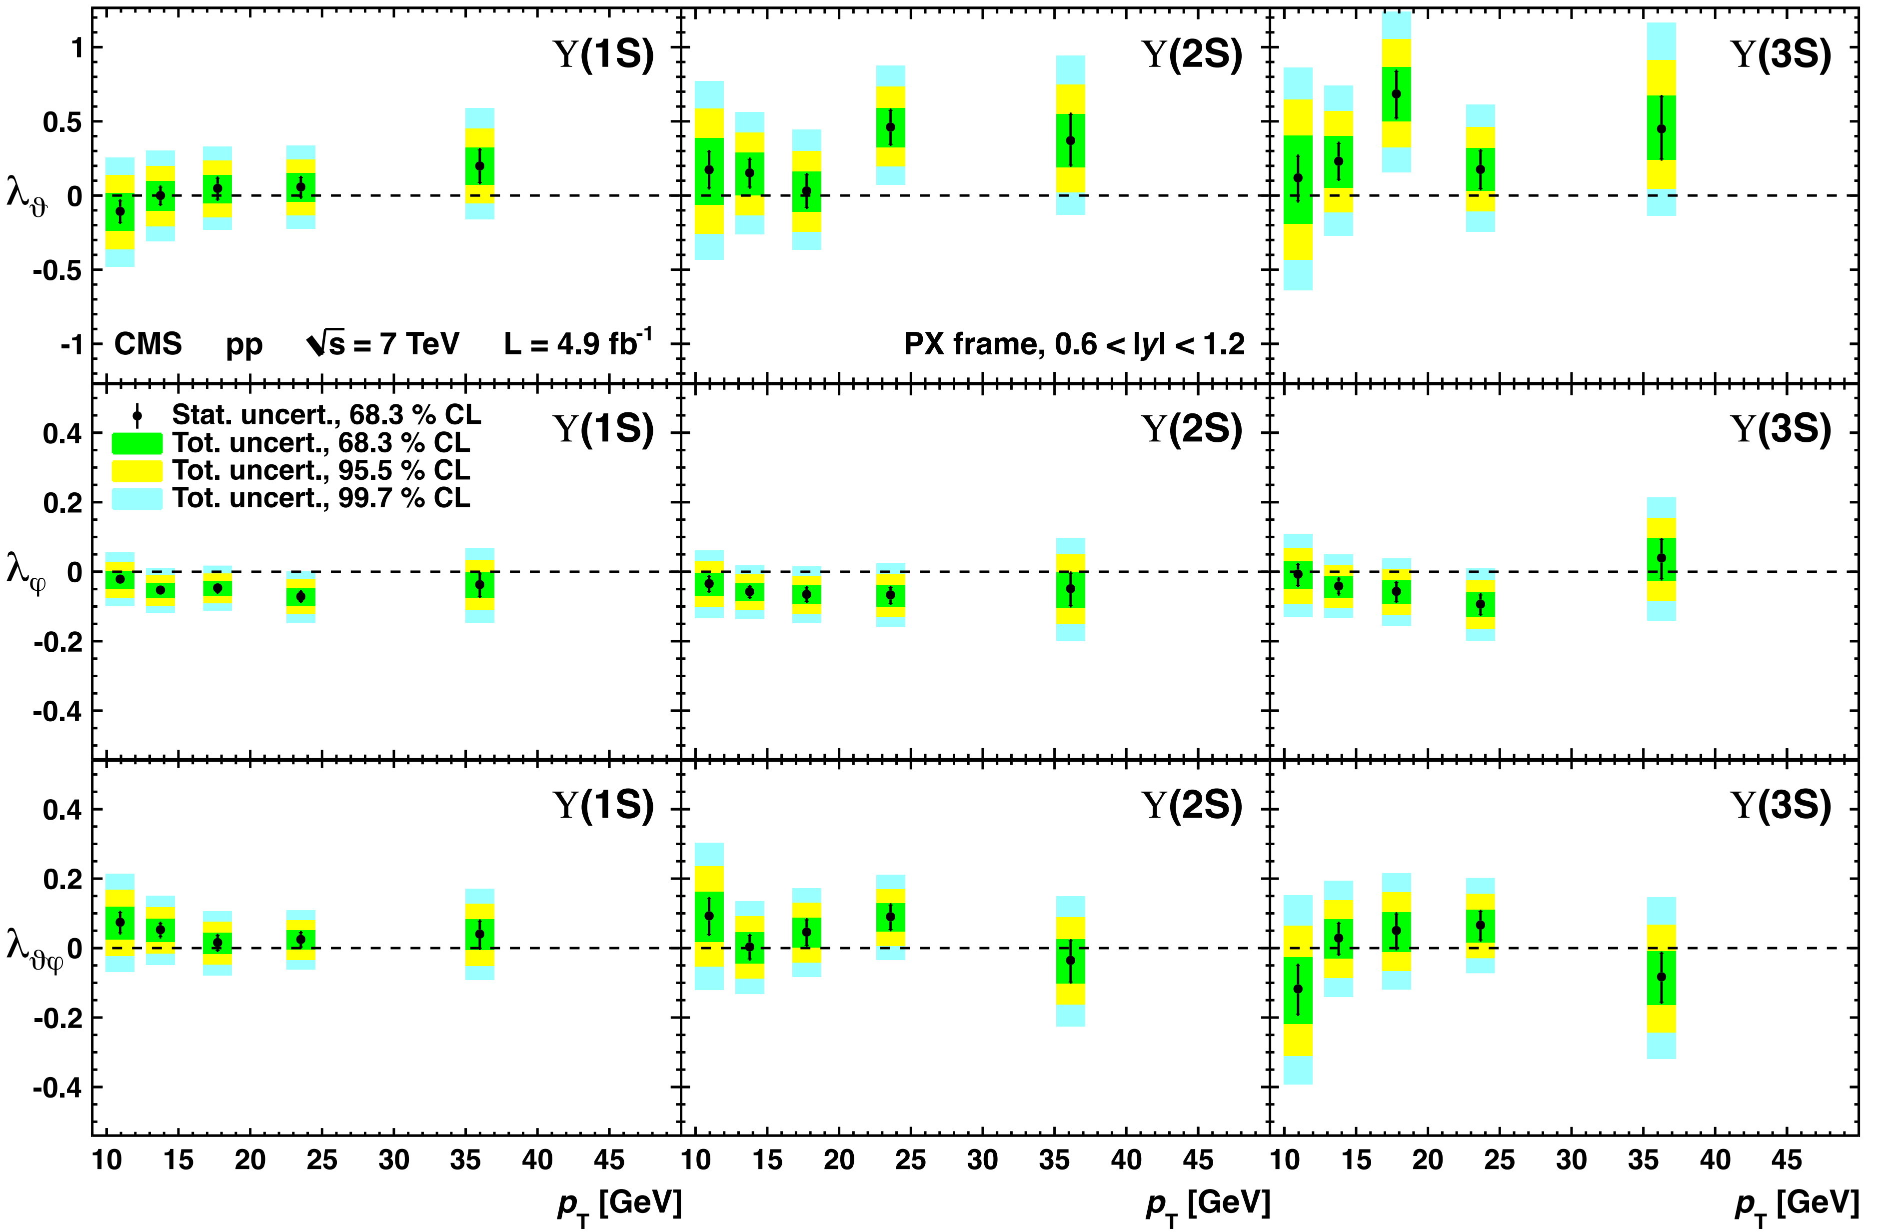
Systematic Effects

- Sources of systematic effects:
  - Analysis method
  - Background model
  - Muon efficiencies
- Systematic uncertainties are propagated to the PPD
- Total uncertainties of the measurements are dominated by systematics at low p_T and statistics at high p_T
- Υ(2S) and Υ(3S) systematic uncertainties are dominated by the background model uncertainty, especially at low p_T

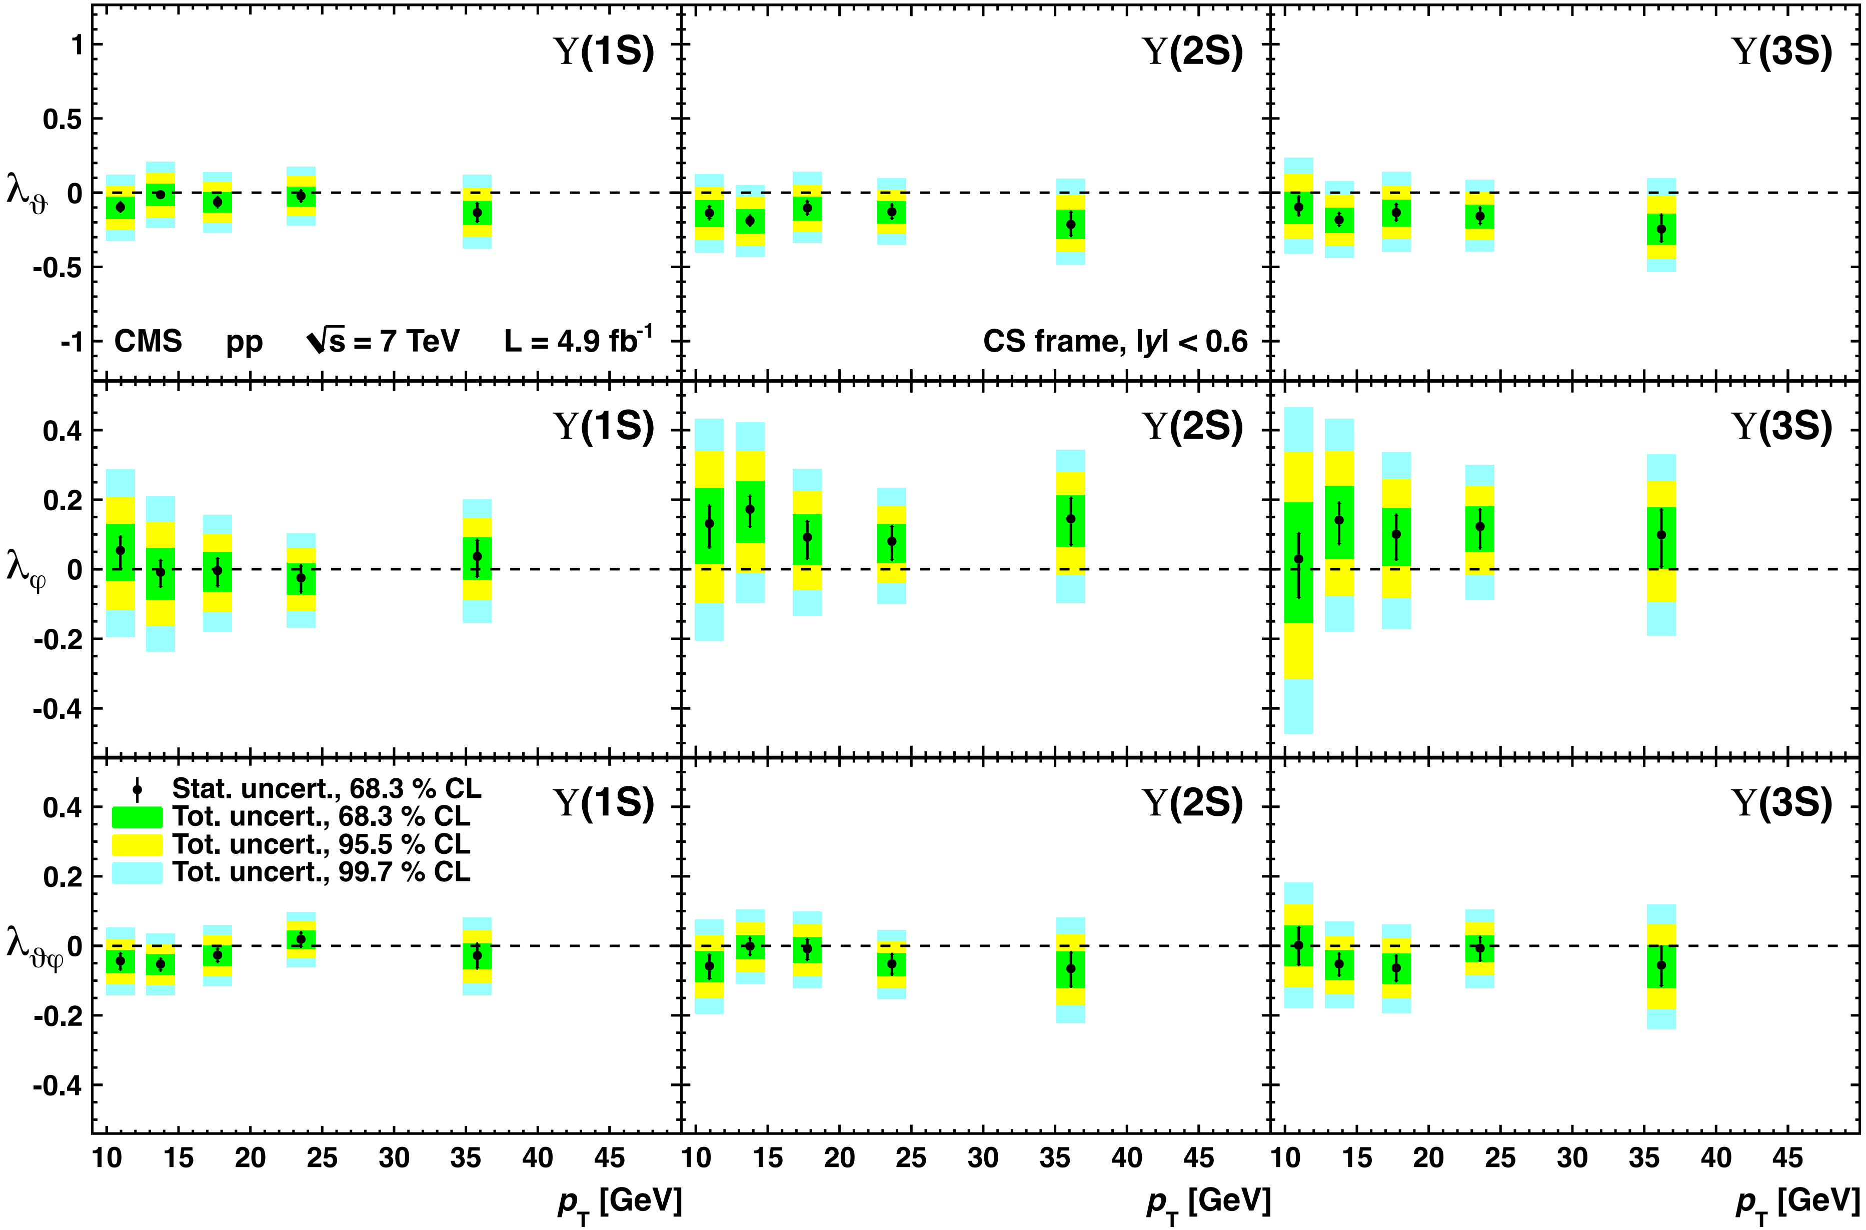
Υ(nS) Polarization in the PX Frame, |y| < 0.6



Υ(nS) Polarization in the PX Frame, 0.6 < |y| < 1.2



ϒ(nS) Polarization in the CS Frame, |y| < 0.6



Υ(nS) Polarization in the CS Frame, 0.6 < |y| < 1.2
