	The study of the fields requires to solve the Maxwell equations in a given structure taking the beam current as source of fields. This is a quite complicated task for which it has been necessary to develop dedicated computer codes, which solve the e.m. problem in the frequency or in the time domain. There are several useful codes for the design of accelerator devices: MAFIA, ABCI, URMEL, etc
Theo	oretical Analysis
therefore desirable to know what	ne particular charge distribution of the beam. It is is the effect of a single charge, i.e. find the Green ct the fields produced by any charge distribution.

The passage of the impulsive current charges only the capacitor, which changes its potential by an amount $V_c(0)$.

This potential will oscillate and decay producing a current flow in the resistor and inductance.

For t > 0 the potential satisfy the following equation and initial conditions:

$$\vec{V} + \frac{1}{RC}\vec{V} + \frac{1}{LC}V = 0$$

$$V(t = 0^{+}) = \frac{q}{C} = V_{0}$$

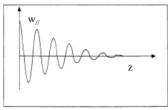

$$\vec{V}(t = 0^{+}) = \frac{\dot{q}}{C} = \frac{I(0^{+})}{C} = \frac{V_{0}}{RC}$$

$$V(t) = V_{0}e^{-\gamma t} \left[\cos(\overline{\omega}t) - \frac{\gamma}{\overline{\omega}}\sin(\overline{\omega}t)\right]$$

$$\overline{\omega}^{2} = \omega_{r}^{2} - \gamma^{2} \quad 2\gamma = 1/RC \quad \omega_{r}^{2} = 1/LC$$

putting z = -ct (z is negative behind the charge),

$$w_{//}(z) = \frac{-V(z)}{q} = w_0 e^{\gamma z/c} \left[\cos(\overline{\omega}z/c) + \frac{\gamma}{\overline{\omega}} \sin(\overline{\omega}z/c) \right]$$

It is also useful to define the *loss factor* as the normalised energy lost by the source charge q

$$k = -\frac{U(z=0)}{q^2}$$

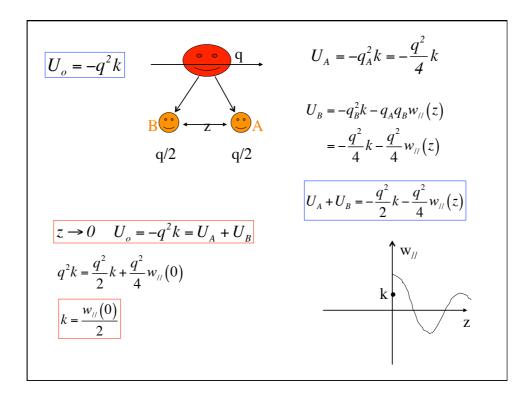

Although in general the loss factor is given by the longitudinal wake at z=0, for charges travelling with the light velocity the longitudinal wake potential is discontinuous at z=0

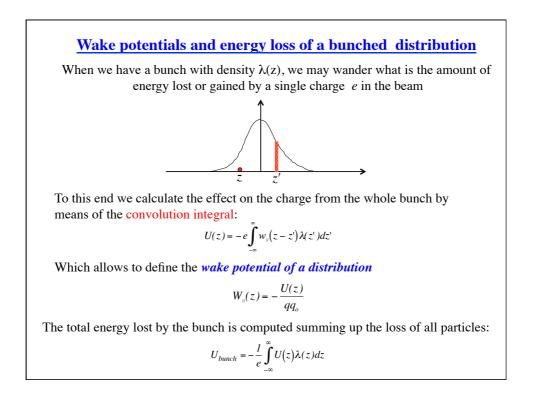

The exact relationship between k and w(z=0) is given by the *beam loading theorem*:

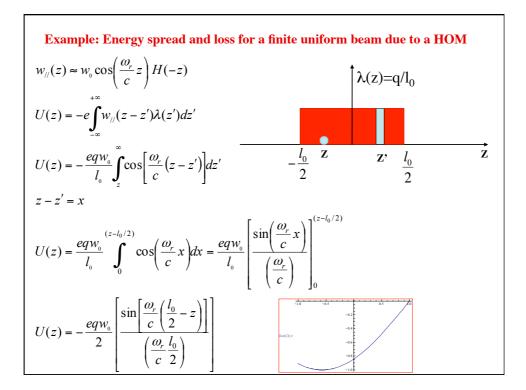

$$k = \frac{w_{\prime\prime}(z \rightarrow 0)}{2}$$

$$k = \frac{w_{\prime\prime}(z \rightarrow 0)}{z}$$

Causality requires that the longitudinal wake potential of a charge travelling with the velocity of light is discontinuous at the origin.

Parasitic loss

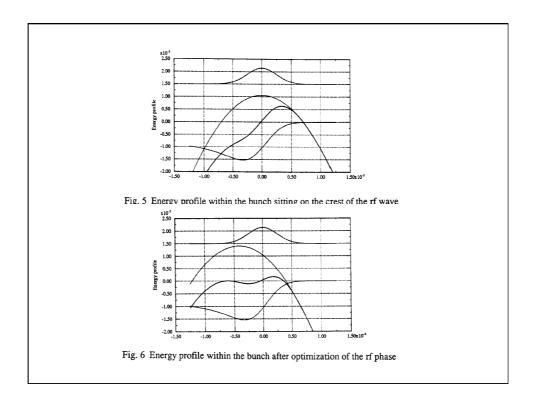

$$U_{bunch} = \frac{1}{e} \int_{-\infty}^{+\infty} U(z') \lambda(z') dz' \approx \frac{-q^2 w_0}{2l_0 \left(\frac{\omega_r}{c} \frac{l_0}{2}\right)} \int_{-\frac{l_0}{2}}^{\frac{l_0}{2}} \sin\left[\frac{\omega_r}{c} \left(\frac{l_0}{2} - z'\right)\right] dz'$$

$$U_{bunch} = \frac{-q^2 w_0 c}{\omega_r l_0^2} \left|\frac{-\cos\left[\frac{\omega_r}{c} \left(\frac{l_0}{2} - z'\right)\right]}{-\frac{\omega_r}{c}}\right|_{-\frac{l_0}{2}}^{\frac{l_0}{2}}$$

$$U_{bunch} = -\frac{q^2 w_0 c^2}{\omega_r^2 l_0^2} \left[1 - \cos\left(\frac{\omega_r l_0}{c}\right)\right] = -\frac{2q^2 w_0 c^2}{\omega_r^2 l_0^2} \sin^2\left(\frac{\omega_r l_0}{2c}\right)$$

$$U_{bunch} = -\frac{q^2 w_0}{2} \frac{\sin^2\left(\frac{\omega_r l_0}{2c}\right)}{\left(\frac{\omega_r l_0}{2c}\right)^2}$$

$$\lim_{l_0 \to 0} (U_{bunch}) = -\frac{q^2 w_0}{2}$$

Coupling Impedance

The wake potentials are used for to study the beam dynamics in the time domain (s=vt). If we take the equation of motion in the frequency domain, we need the Fourier transform of the wake potentials. Since these quantities have Ohms units are called *coupling impedances*:

Longitudinal impedance (Ω)

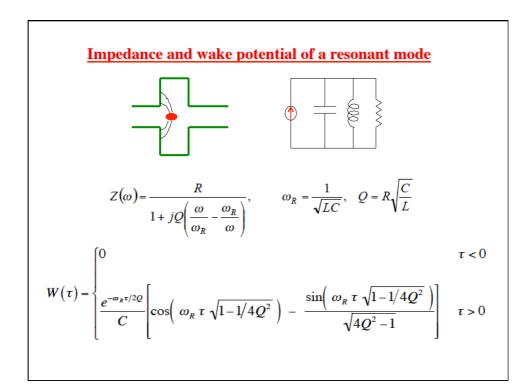

$$Z_{//}(\omega) = \frac{1}{v} \int_{-\infty}^{\infty} w_{//}(z) e^{-i\frac{\omega z}{v}} dz$$

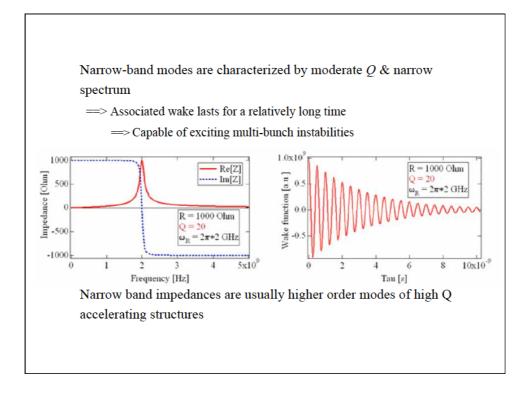

Transverse impedance (Ω/m)

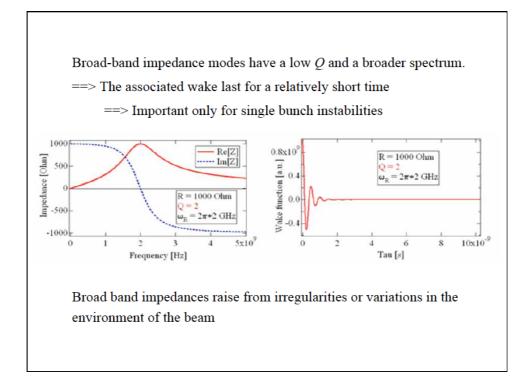

$$\boldsymbol{Z}_{\perp}(\omega) = \frac{i}{v} \int_{-\infty}^{\infty} \boldsymbol{w}_{\perp}(z) e^{-i\frac{\omega z}{v}} dz$$

 Z_R is responsible for the energy losses

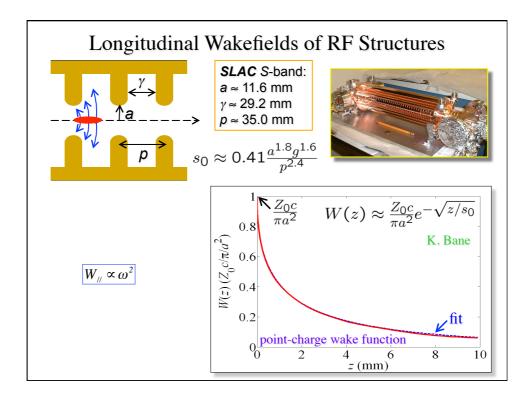

Z_i defines the phase between the beam response & exciting wake potential

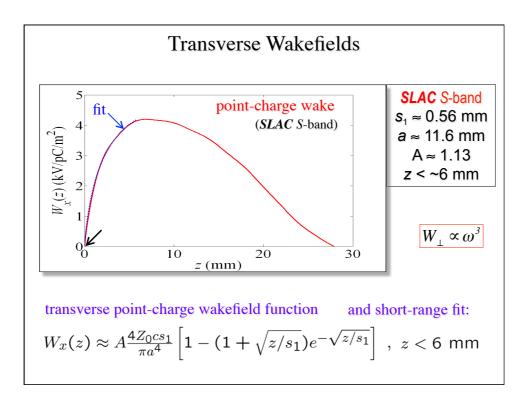

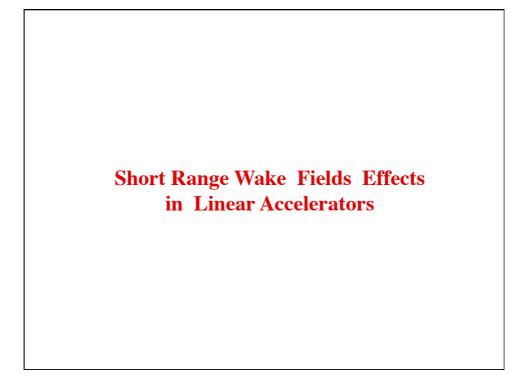

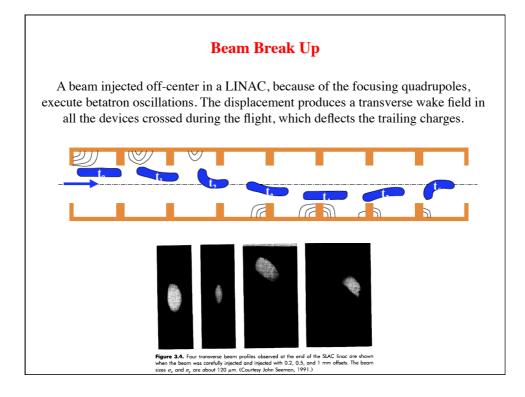

In order to understand the effect, we consider a simple model with only two charges $q_1 = Ne/2$ (leading = half bunch) and $q_2 = e$ (trailing = single charge). $q_2 = e$ (railing = Ne/2)(railing = Ne/2)

$$y_1(s) = \hat{y}_1 \cos\left(\frac{\omega_y}{c}s\right); \quad \frac{\omega_y}{c} = \frac{2\pi}{\lambda_w}$$

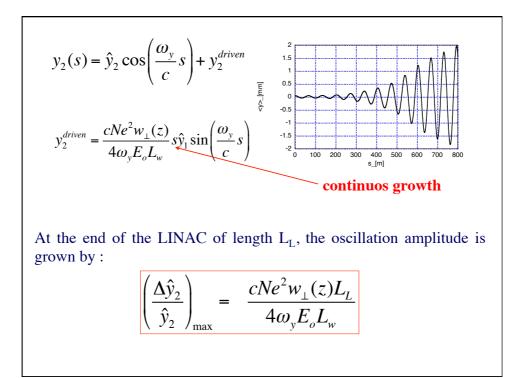

the trailing charge, at a distance z behind, over a length L_w experiences a deflecting force proportional to the displacement y_1 , and dependent on the distance z:

$$\left\langle F_{y}^{wake}(z, y_{1})\right\rangle = \frac{Ne^{2}}{2L_{w}}w_{\perp}(z)y_{1}(s)$$

This force drives the motion of the trailing charge:

$$y_{2}'' + \left(\frac{\omega_{y}}{c}\right)^{2} y_{2} = \frac{Ne^{2}w_{\perp}(z)}{2\beta^{2}E_{o}L_{w}} \hat{y}_{1}\cos\left(\frac{\omega_{y}}{c}s\right)$$

This is the typical equation of a resonator driven at the resonant frequency. The solution is given by the superposition of the "free" oscillation and a "driven" oscillation which, being driven at the resonant frequency, grows linearly with s.

Balakin-Novokhatsky-Smirnov Damping

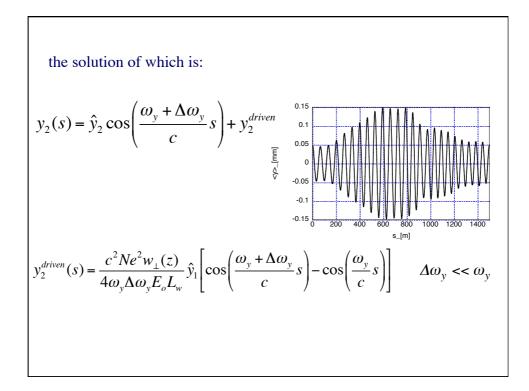

The BBU instability is quite harmful and hard to take under control even at high energy with a strong focusing, and after a careful injection and steering.

A simple method to cure it has been proposed observing that the strong oscillation amplitude of the bunch tail is mainly due to the **"resonant"** driving.

If the tail and the head move with a different frequency, this effect can be significantly removed.

Let us assume that the tail oscillate with a frequency $\omega_y + \Delta \omega_y$, the equation of motion reads:

$$y_2'' + \left(\frac{\omega_y + \Delta \omega_y}{c}\right)^2 y_2 = \frac{Ne^2 w_\perp(z)}{2\beta^2 E_o L_w} \hat{y}_1 \cos\left(\frac{\omega_y}{c}s\right)$$

by a suitable choice of $\Delta \omega_y$, it is possible to fully depress the oscillations of the tail.

$$y_{2}(s) = \hat{y}_{1} \cos\left(\frac{\omega_{y}}{c}s\right)$$
$$\Delta \omega_{y} = \frac{c^{2}Ne^{2}w_{\perp}(z)}{4\omega_{y}E_{o}L_{w}}$$
$$\hat{y}_{2} = \hat{y}_{1}$$

Exploit the **energy spread** across the bunch which, because of the chromaticity, induces a spread in the betatron frequency. An energy spread correlated with the position is attainable with the external accelerating voltage, or with the wake fields.

$$\frac{\Delta\omega_{y}}{\omega_{y}} = -\frac{\Delta\gamma}{\gamma}$$

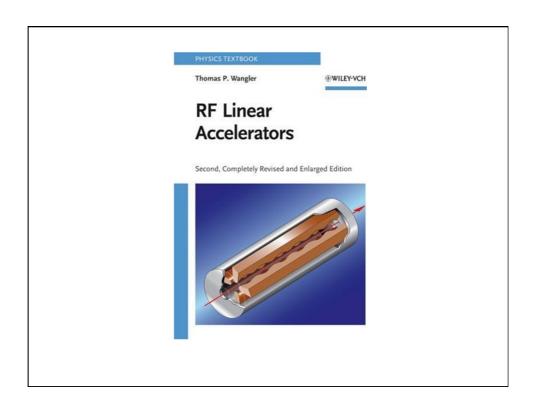

More general model including charge distribution and acceleration

$$\frac{\partial}{\partial s} \left[\gamma(s) \frac{\partial y(z,s)}{\partial s} \right] + k_y^2(s) \gamma(s) y(z,s) = -\frac{e^2 N_p}{m_0 c^2 L_w} \int_z^\infty y(s,z') w_\perp(z'-z) \lambda(z') dz'$$

$$y(L_L) = y_m \sqrt{\frac{\gamma_i}{6\pi\gamma_f}} \eta^{-1/6} \exp\left[\frac{3\sqrt{3}}{4} \eta^{1/3}\right] \cos\left[k_y L_L - \frac{3}{4} \eta^{1/3} + \frac{\pi}{12}\right]$$

$$\eta = \frac{e^2 N_p}{k_y (dE_0 / ds)} \frac{w_{\perp 0}}{L_w} ln\left(\frac{\gamma_f}{\gamma_i}\right)$$

Instabilities : driven oscillators

Consider an harmonic oscillator with natural frequency $\omega,$ with an external excitation at frequency Ω

$$\ddot{x} + \omega^2 x = A \cos(\Omega t)$$
General solution:
$$x(t) = x^{free}(t) + x^{driven}(t)$$

$$\cos(\Omega t) \Rightarrow e^{i\Omega t}$$

$$x^{free}(t) = \tilde{x}_m^f e^{i\omega t}$$

$$x^{driven}(t) = \tilde{x}_m^d e^{i\Omega t}$$

substitution in the diff. equation:

$$(\omega^{2} - \Omega^{2})\tilde{x}_{m}^{d}e^{i\Omega t} = Ae^{i\Omega t}$$
$$x^{driven}(t) = \frac{A}{(\omega^{2} - \Omega^{2})}e^{i\Omega t}$$

The general solution has to satisfy the initial condition at t=0. In our case we assume that the oscillator is at rest for t=0:

. .

$$x^{free} (t = 0) = -x^{driven} (t = 0)$$
$$\tilde{x}_m^f = -\frac{A}{\omega^2 - \Omega^2}$$

thus we get:

$$x(t) = \frac{A}{\omega^2 - \Omega^2} \Big[e^{i\Omega t} - e^{i\omega t} \Big]$$

taking only the real part:

$$x(t) = \frac{A}{\omega^2 - \Omega^2} \Big[\cos(\Omega t) - \cos(\omega t) \Big]$$
