Nailing Natural SUSY: Higgsino Parameter Determination at the ILC

P_T Spectrum of Decay Fermions

Tracking Efficiency vs P

→ 500 GeV

and pair background

1.5 2 P_T/GeV

 $\bigcap_{i=1}^{\infty} \widetilde{\chi}_{1}^{+} \widetilde{\chi}_{1}^{-} \gamma$

 $\widetilde{\chi}_1^0 \widetilde{\chi}_2^0 \gamma$

Mikael Berggren, Felix Brümmer, Jenny List, Gudrid-Moortgat-Pick, Tania Robens, Krzysztof Rolbiecki, <u>Hale Sert</u> on behalf of the ILD Concept Group

Natural SUSY

$$M_Z^2 = 2\frac{m_{H_u}^2 \tan^2 \beta - m_{H_d}^2}{1 - \tan^2 \beta} - 2|\mu|^2$$

Naturalness requires μ parameter at the electroweak scale which arises light higgsinos

- The higgsinos are almost mass degenerate, mass differences between them are around a few GeV
- ➤ All other SUSY particles are heavy up to a few TeV
- > Two production processes can be used to detect such light and degenerate higgsinos at the ILC

$$ightharpoonup e^+e^-
ightarrow \tilde{\chi}_1^+ \, \tilde{\chi}_1^-$$

$$ightharpoonup e^+e^-
ightarrow \tilde{\chi}_1^0 \, \tilde{\chi}_2^0$$

where
$$\tilde{\chi}_1^\pm o \tilde{\chi}_1^0 \ W^{\pm *}$$
 and $\tilde{\chi}_2^0 o \tilde{\chi}_1^0 \ Z^{0*}$ or $\tilde{\chi}_2^0 o \tilde{\chi}_1^0 \ \gamma$

Signatures of the higgsinos

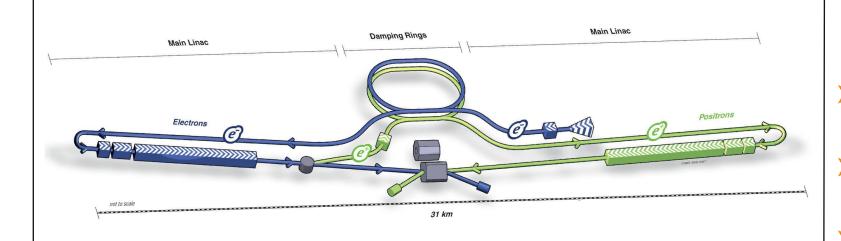

- \triangleright A few soft visible particles ($P_T < 2 \text{ GeV}$)
- \triangleright Lots of missing energy due to $\tilde{\chi}_1^0$
- > This scenario is challenging for the LHC, since to resolve such degenerate particles is not easy
- ➤ However, it is possible to do this analysis at the ILC

ILC

International Linear Collider

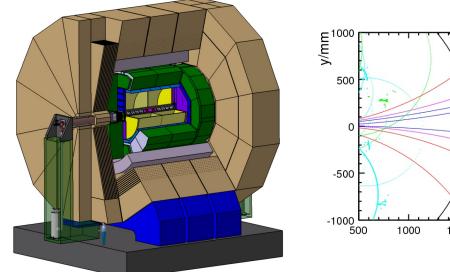

ILC is a planned electron-positron collider. Planned design properties:

- $\succ E_{CM} = 200$ 500 GeV (upgradable to 1 TeV)
- $ightharpoonup \int \mathcal{L}dt/year = 250 \ fb^{-1}$
- $P(e^{-}) = 80\%, P(e^{+}) = 30 60\%$

ILD

International Large Detector

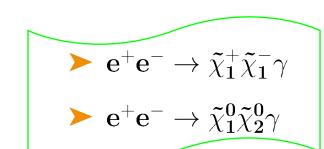

- > ILD has an excellent tracking and finely-grained calorimetry systems
- > This gives ILD the ability to reconstruct the energy of individual particles [Particle Flow Approach]
- Samples run with ILD fast simulation (SGV)

■ SM

simul. data

Requirement of Hard ISR Photon

- > Hard Initial State Radiation (ISR) photon is required to avoid similarity of the signal final state with some of the SM background
- > It also makes it possible to use the recoil mass method for the mass measurement

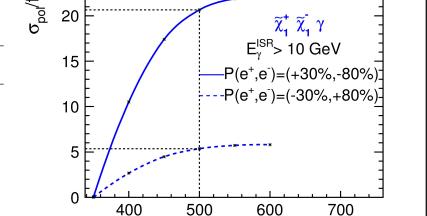

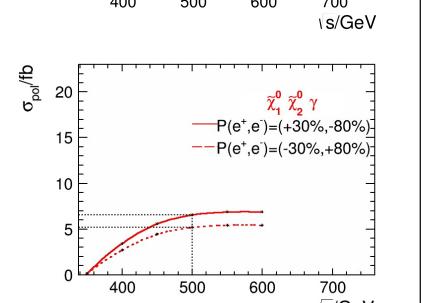

Benchmark Point

- $ightharpoonup \Delta M(\tilde{\chi}_1^{\pm}, \tilde{\chi}_1^0) = 0.77 \text{ GeV}$
- $ightharpoonup \Delta M(\tilde{\chi}_{2}^{0}, \tilde{\chi}_{1}^{0}) = 1.04 \text{ GeV}$

Analysis Overview: Analysis is performed

- $ightharpoonup E_{CM} = 500 \text{ GeV}$
- $ightharpoonup \int \mathcal{L}dt = 500 \ fb^{-1}$
- Two different polarisation combinations are considered;
 - $P(e^+, e^-) = (+30\%, -80\%)$
- $P(e^+, e^-) = (-30\%, +80\%)$
- > Polarised cross sections can be seen from the plots on the right side

Event Selection

To suppress SM background pre-selection is applied;

Pre-selection:

- > Hard ISR photon is required in each event > High energetic electrons in the very forward region are excluded
- $\succ E_{\rm decay\ products} < 5\ {\rm GeV},\ E_{miss} > 300\ {\rm GeV}$
- > Both decay products and missing energy are required not to be in the very forward region

To separate signals exclusive decay modes are chosen;

 $\tilde{\chi}_1^{\pm}$ Mass Measurement

 $M_{\rm gr}^{\rm fit}$ = 168.6 ± 1.0 GeV

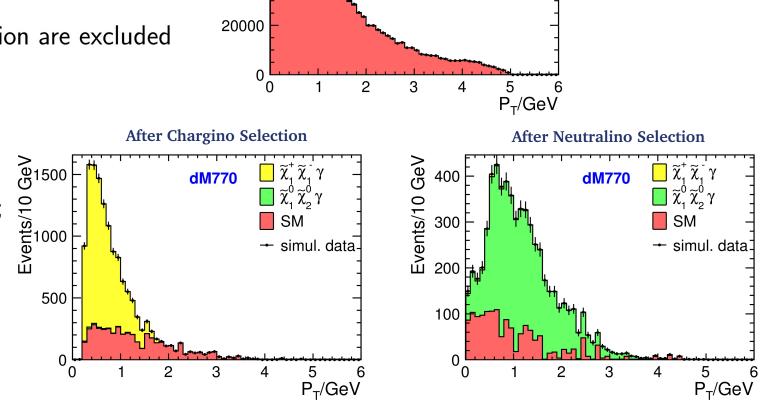

Chargino Selection: \triangleright Semileptonic final state $(\pi + e/\mu)$

Neutralino Selection:

 \triangleright Photonic final state (γ)

After Pre-Selection

Measurement Procedure

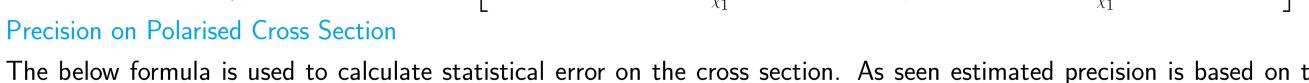

$\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$ Mass Measurement

Recoil mass of hard ISR photon is used to calculate mass of the higgsinos

 $\blacktriangleright \sqrt{s'} = s - 2\sqrt{s}E^{\gamma}$

At the rest frame of the higgsinos, $\sqrt{s'} = 2 \times M_{\tilde{v}}$ Mass Difference Measurement $(\Delta M(\tilde{\chi}_1^{\pm}, \tilde{\chi}_1^0))$

used. Because at the rest frame of the chargino, the neutralino is also produced at rest and mass difference between them gives the energy of decay products of the W boson $\left[E_{\pi}^* = \frac{(M_{\tilde{\chi}_1}^{\pm} - M_{\tilde{\chi}_1}^0)(M_{\tilde{\chi}_1}^{\pm} + M_{\tilde{\chi}_1}^0) + m_{\pi}^2}{2M_{\tilde{\chi}_1}^{\pm}} = \frac{1}{1/\Delta M + 1/\Sigma M} + \frac{m_{\pi}^2}{2M_{\tilde{\chi}_1}^{\pm}}, \quad E_{\pi}^* \approx \Delta M \right]$ $\succ E_{\pi}^* = \frac{(\sqrt{s} - E^{\gamma})E^{\pi} + \mathbf{P}^{\pi} \cdot \mathbf{P}^{\gamma}}{\sqrt{s'}}$

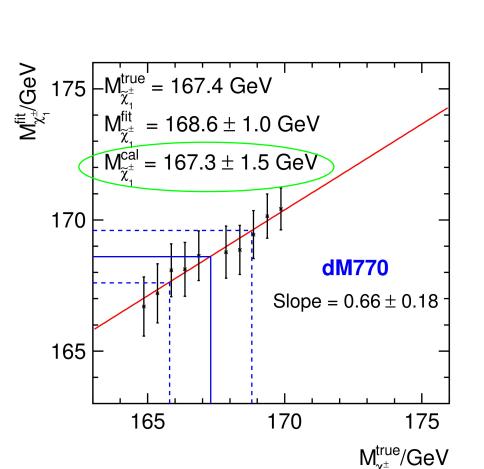

The below formula is used to calculate statistical error on the cross section. As seen estimated precision is based on the efficiency and purity $ightharpoonup \frac{\langle \delta \sigma_{meas} \rangle}{\langle \sigma_{meas} \rangle} = \frac{1}{\sqrt{\epsilon \cdot \pi \cdot \int \mathcal{L} dt \cdot \sigma_{signal}}}$

300 350 √s'/GeV Reduced CM energy distribution for the chargino mass Fitting is done in the following order:

- > SM is fitted with an exponential function assuming that SM background is known precisely
- > SM background is fixed
- \triangleright SM + signals are fitted using linear function for signal

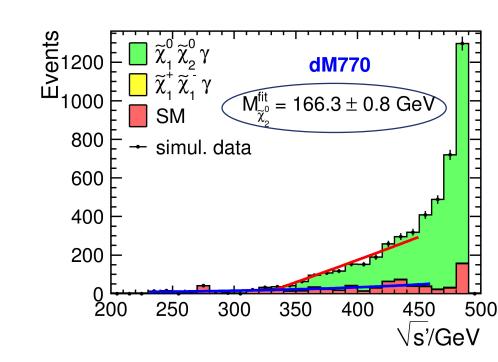

Calibration curve for the chargino mass

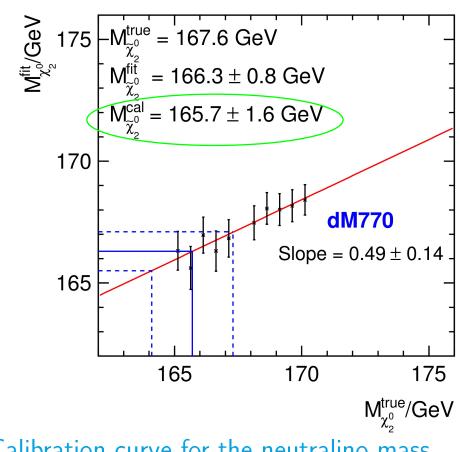

Since the method is an approximation in some sense, the fitted higgsino masses have been calibrated ➤ The chargino mass can be measured with 1.5 GeV

statistical uncertainty

$\tilde{\chi}_{2}^{0}$ Mass Measurement

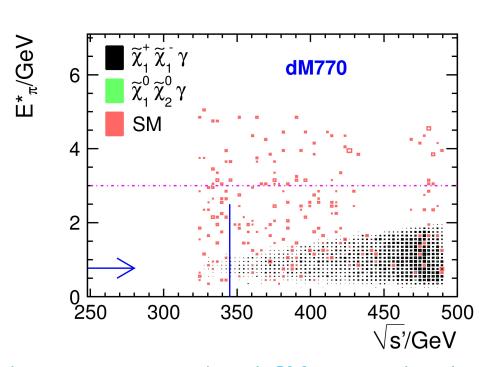

Calibration curve for the neutralino mass

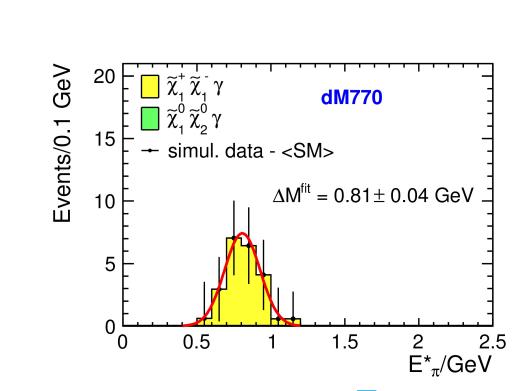

> The neutralino mass can be measured with 1.6 GeV statistical uncertainty

Mass Difference Measurement

Boosted energy versus reduced CM energy distribution

- > Tip point of the triangular shape gives the mass difference. Blue arrow shows the true mass difference
- > A cut on the reduced CM energy is applied to examine the region around tip, which is shown with blue line

Boosted energy distribution after $\sqrt{s'} < 345$ GeV cut Mass difference can be obtained by applying a gaussian fit

to this distribution

➤ The mass difference can be measured with 40 MeV statistical uncertainity

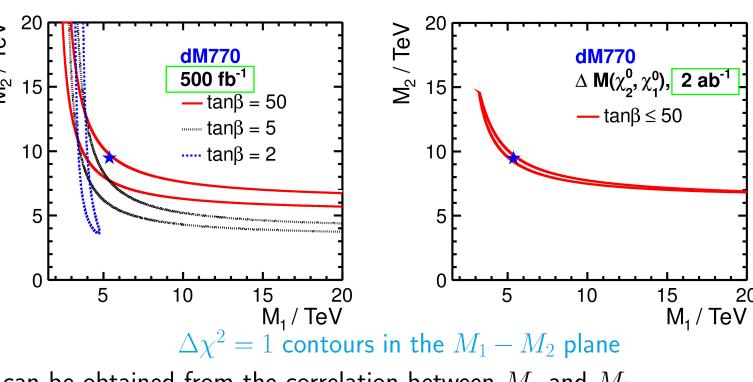

Statistical Precision on Polarised Cross Sections

Polarisations	$P(e^+, e^-) = (+30\%, -80\%)$		$P(e^+, e^-) = (-30\%, -80\%)$	
Processes	$\tilde{\chi}_1^+ \tilde{\chi}_1^- \gamma$	$ ilde{\chi}_1^0 ilde{\chi}_2^0 \gamma$	$\tilde{\chi}_1^+ \tilde{\chi}_1^- \gamma$	$ ilde{\chi}_1^0 ilde{\chi}_2^0\gamma$
Efficiency $(\epsilon \times BR)$	34.9	23.2	34.9	23.2
Purity(π)	85.3	85.8	56.1	82.5
$\langle \delta \sigma_{meas} angle$	1.6	1 7	3 8	1.0

- > Efficiencies are same for both polarisations
- > Huge difference between purities for both polarizations in the chargino processes are due to the difference between polarised cross sections
- > In terms of the precision on cross sections, cross sections can be measured more precisely using the first polarisation

Parameter Determination-Conclusion

- \rightarrow The light higgsinos which are well motivated $\gtrsim 20$ by naturalness can be observed at the ILC
- > They can be resolved inspite of small mass differences
- > Measurement of the higgsino masses and cross sections can be done with very good statistical precision

- \triangleright Lower limits and allowed regions for M_1 and M_2 can be obtained from the correlation between M_1 and M_2
- \triangleright μ parameter can be determined with 2.5 GeV statistical precision, 1 σ allowed range for μ is [164.8, 167.8] GeV
