

CMS results on boosted objects & jet substructure

Alexander Schmidt (University of Hamburg)
on behalf of the CMS Collaboration

HEP 2013
Stockholm
18-24 July 2013

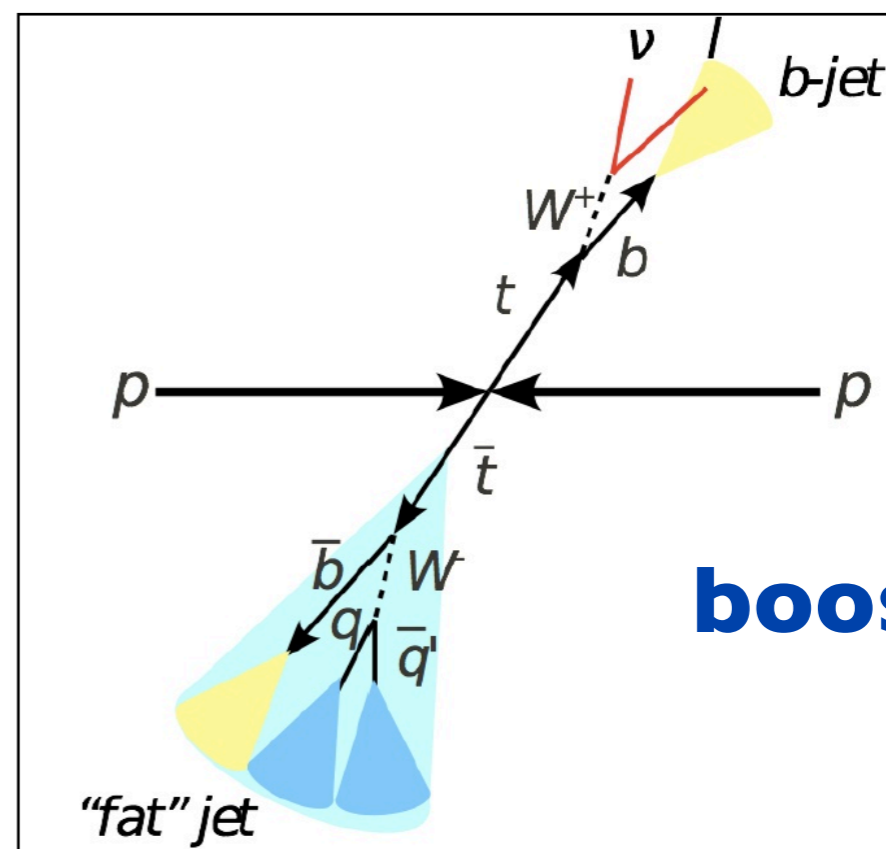

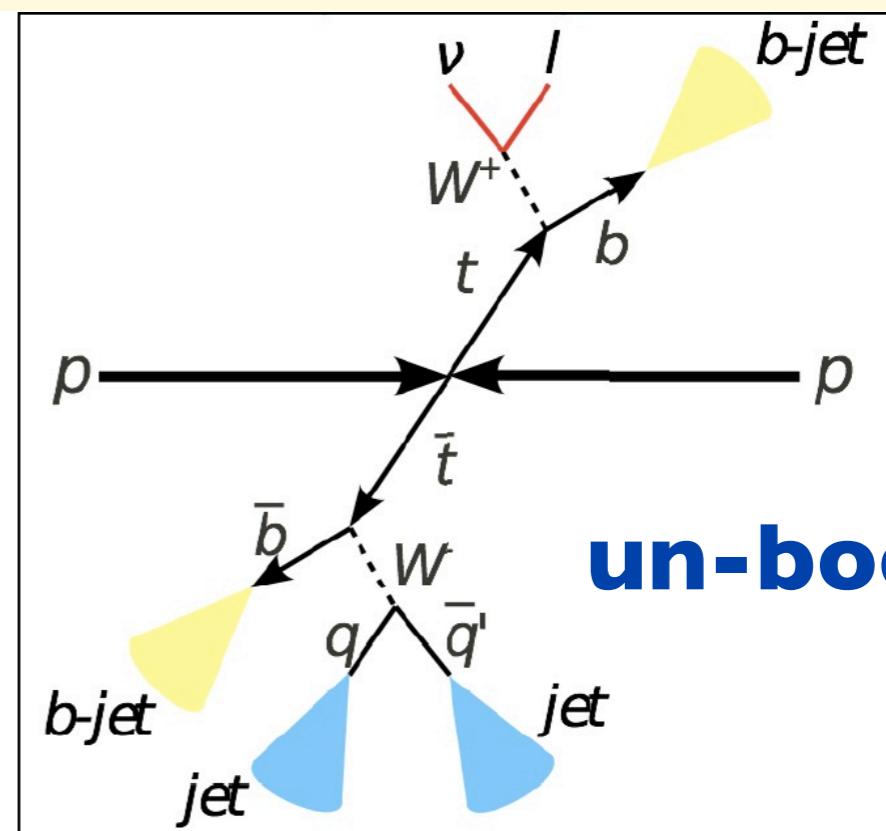

Introduction

domain of ‘classical’ analysis
methods:

- isolated leptons (e.g. relevant for trigger)
- multiple, well separated ‘small’ jets

boosted regime:

- classical methods fail
- dedicated tools to resolve jet-substructure
- top-tagging, H-tagging, W-tagging, ...

W tagging

early efforts in 2010 [CMS PAS JME-10-013]:

- top- and W-tagging algorithms commissioned in CMS with 36pb^{-1}

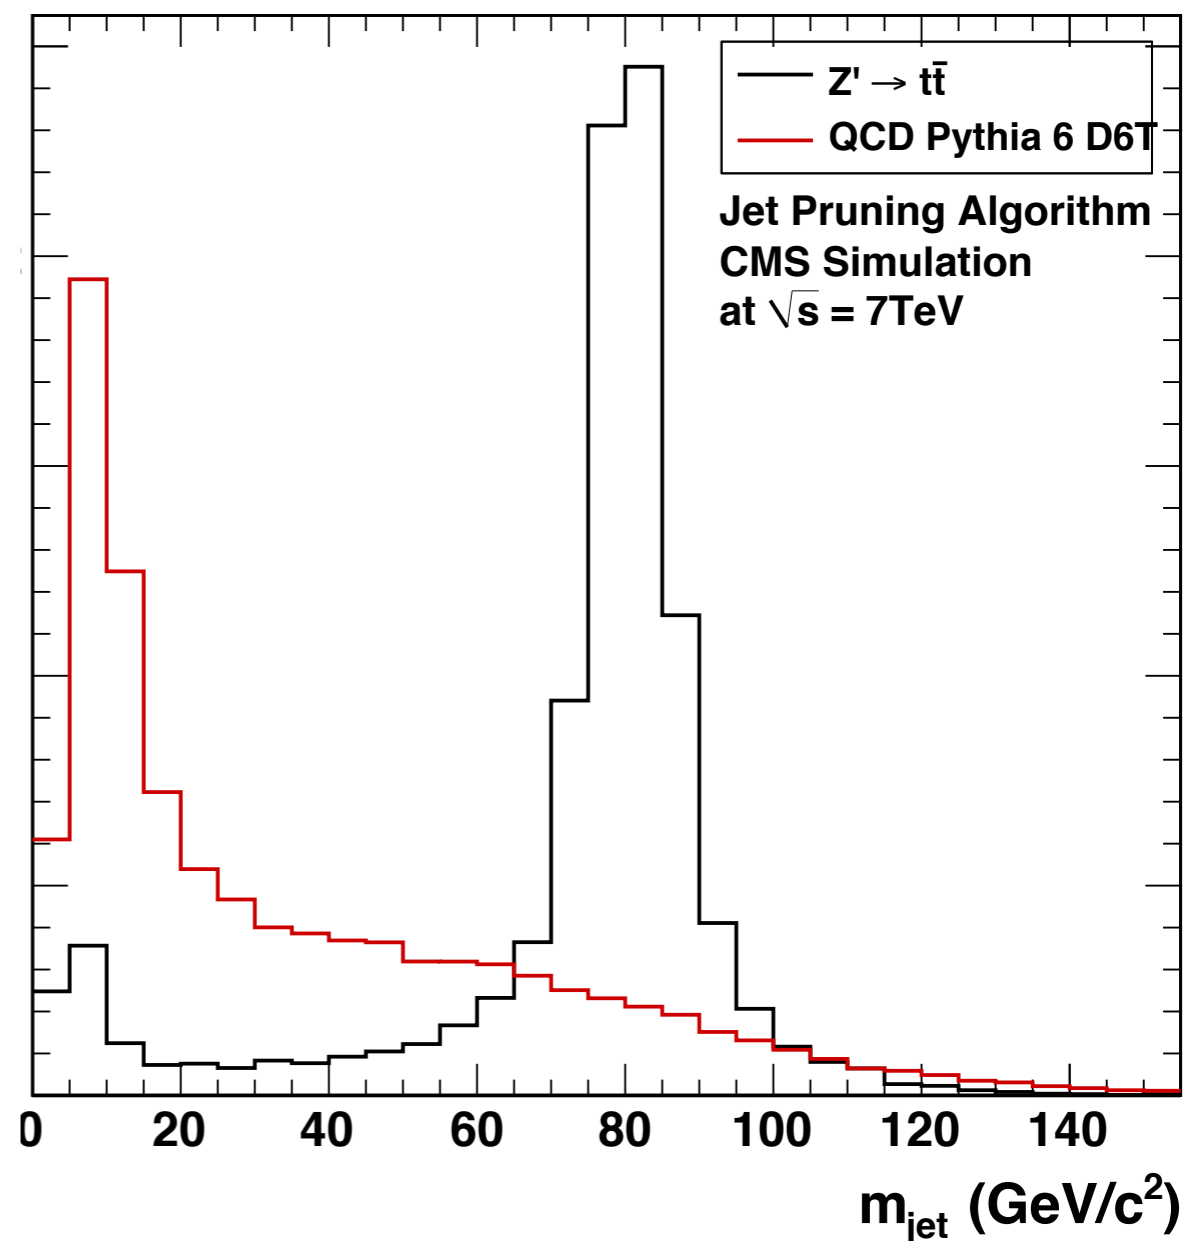

W-tagging [Phys Rev D80 (2009) 051501]:

- starting with Cambridge-Aachen (CA) jets with distance parameter 0.8
- **pruning** removes soft clusters by reclustering the jet with requirements
- at each step of merging clusters i and j into a single cluster p :

$$z_{ij} \equiv \frac{\min(p_{T,i}, p_{T,j})}{p_{T,p}} > z_{\text{cut}}$$

$$\Delta R_{ij} < D_{\text{cut}} = \alpha \times \frac{m_J}{p_T^J}$$

- where $z_{\text{cut}} = 0.1$ and $\alpha=0.5$
- identify W jets by requiring 2 pruned subjets, m_{jet} in $[60, 100]$, mass drop $m_1/m_2 < 0.4$

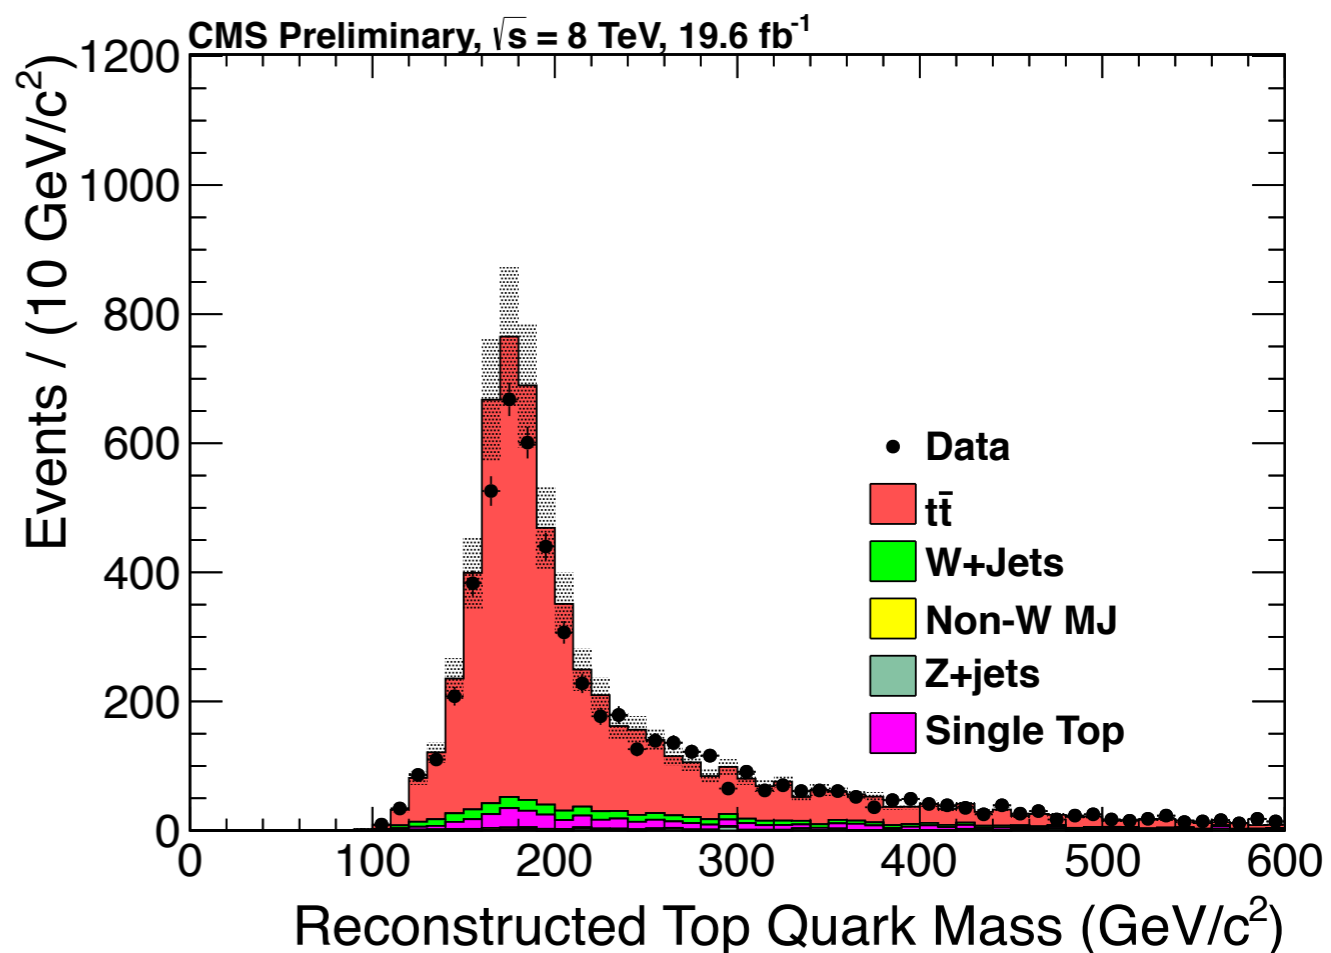

W tagging: in data

high purity top-quark selection with a high-pt muon + jet:

W-tagged jet mass:

W-jet combined with a b-jet:

→ data agree well with simulation

top-tagging

adapted JHU top-tagging algorithm

[PRL 101 (2008) 142001]:

- CA jets with distance parameter 0.8
- reverse clustering sequence, examine clusters pairwise
- continue until separated clusters found

$$\sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} > 0.4 - A \times p_T^C$$

where p_T^C is the parent cluster

- check momentum fraction criterion

$$p_T^{\text{cluster}} > \delta_p \times p_T^{\text{hardjet}} \quad \text{for}$$

to ignore low p_T subclusters

- variables used for top-tagging:

$$140 < m_{\text{jet}} < 250 \text{ GeV}/c^2$$

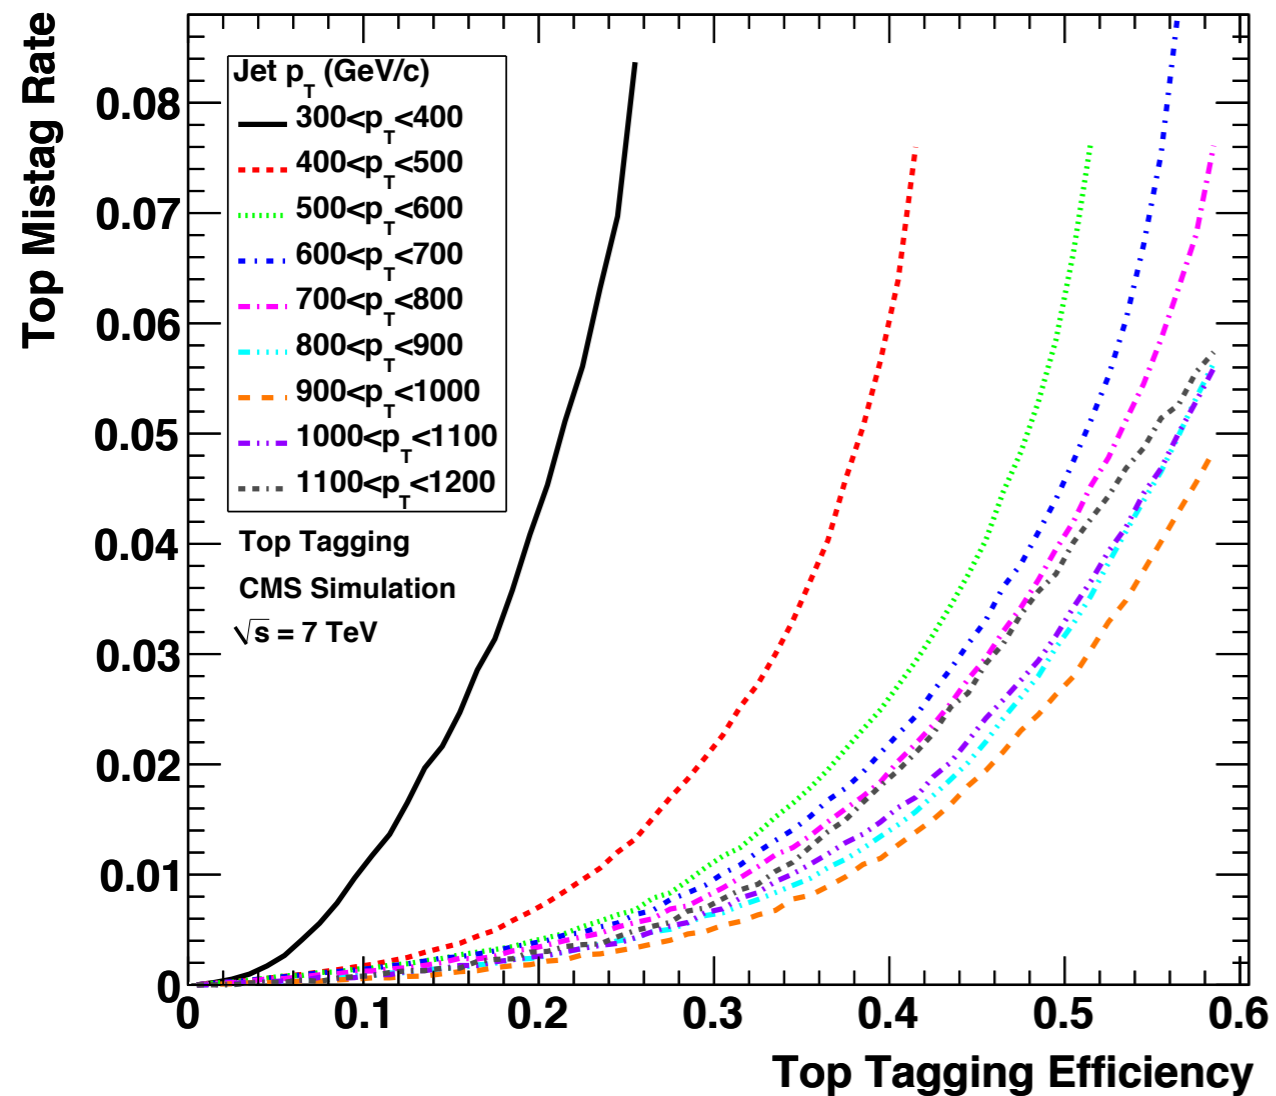

$$N_{\text{subjets}} \geq 3$$

$$m_{\text{min}} > 50 \text{ GeV}/c^2 \quad \text{min pairwise mass}$$

efficiencies and mistag

top-mistag (QCD) vs. efficiency in simulation

data/MC scale factor
for efficiency = 0.93 ± 0.04

mistag from data using top-depleted sample:

- two high- p_T jets, $p_T > 400 \text{ GeV}$
- invert min pairwise requirement of top-tag algorithm for one jet
- if the **other** jet is top-tagged it is mistagged

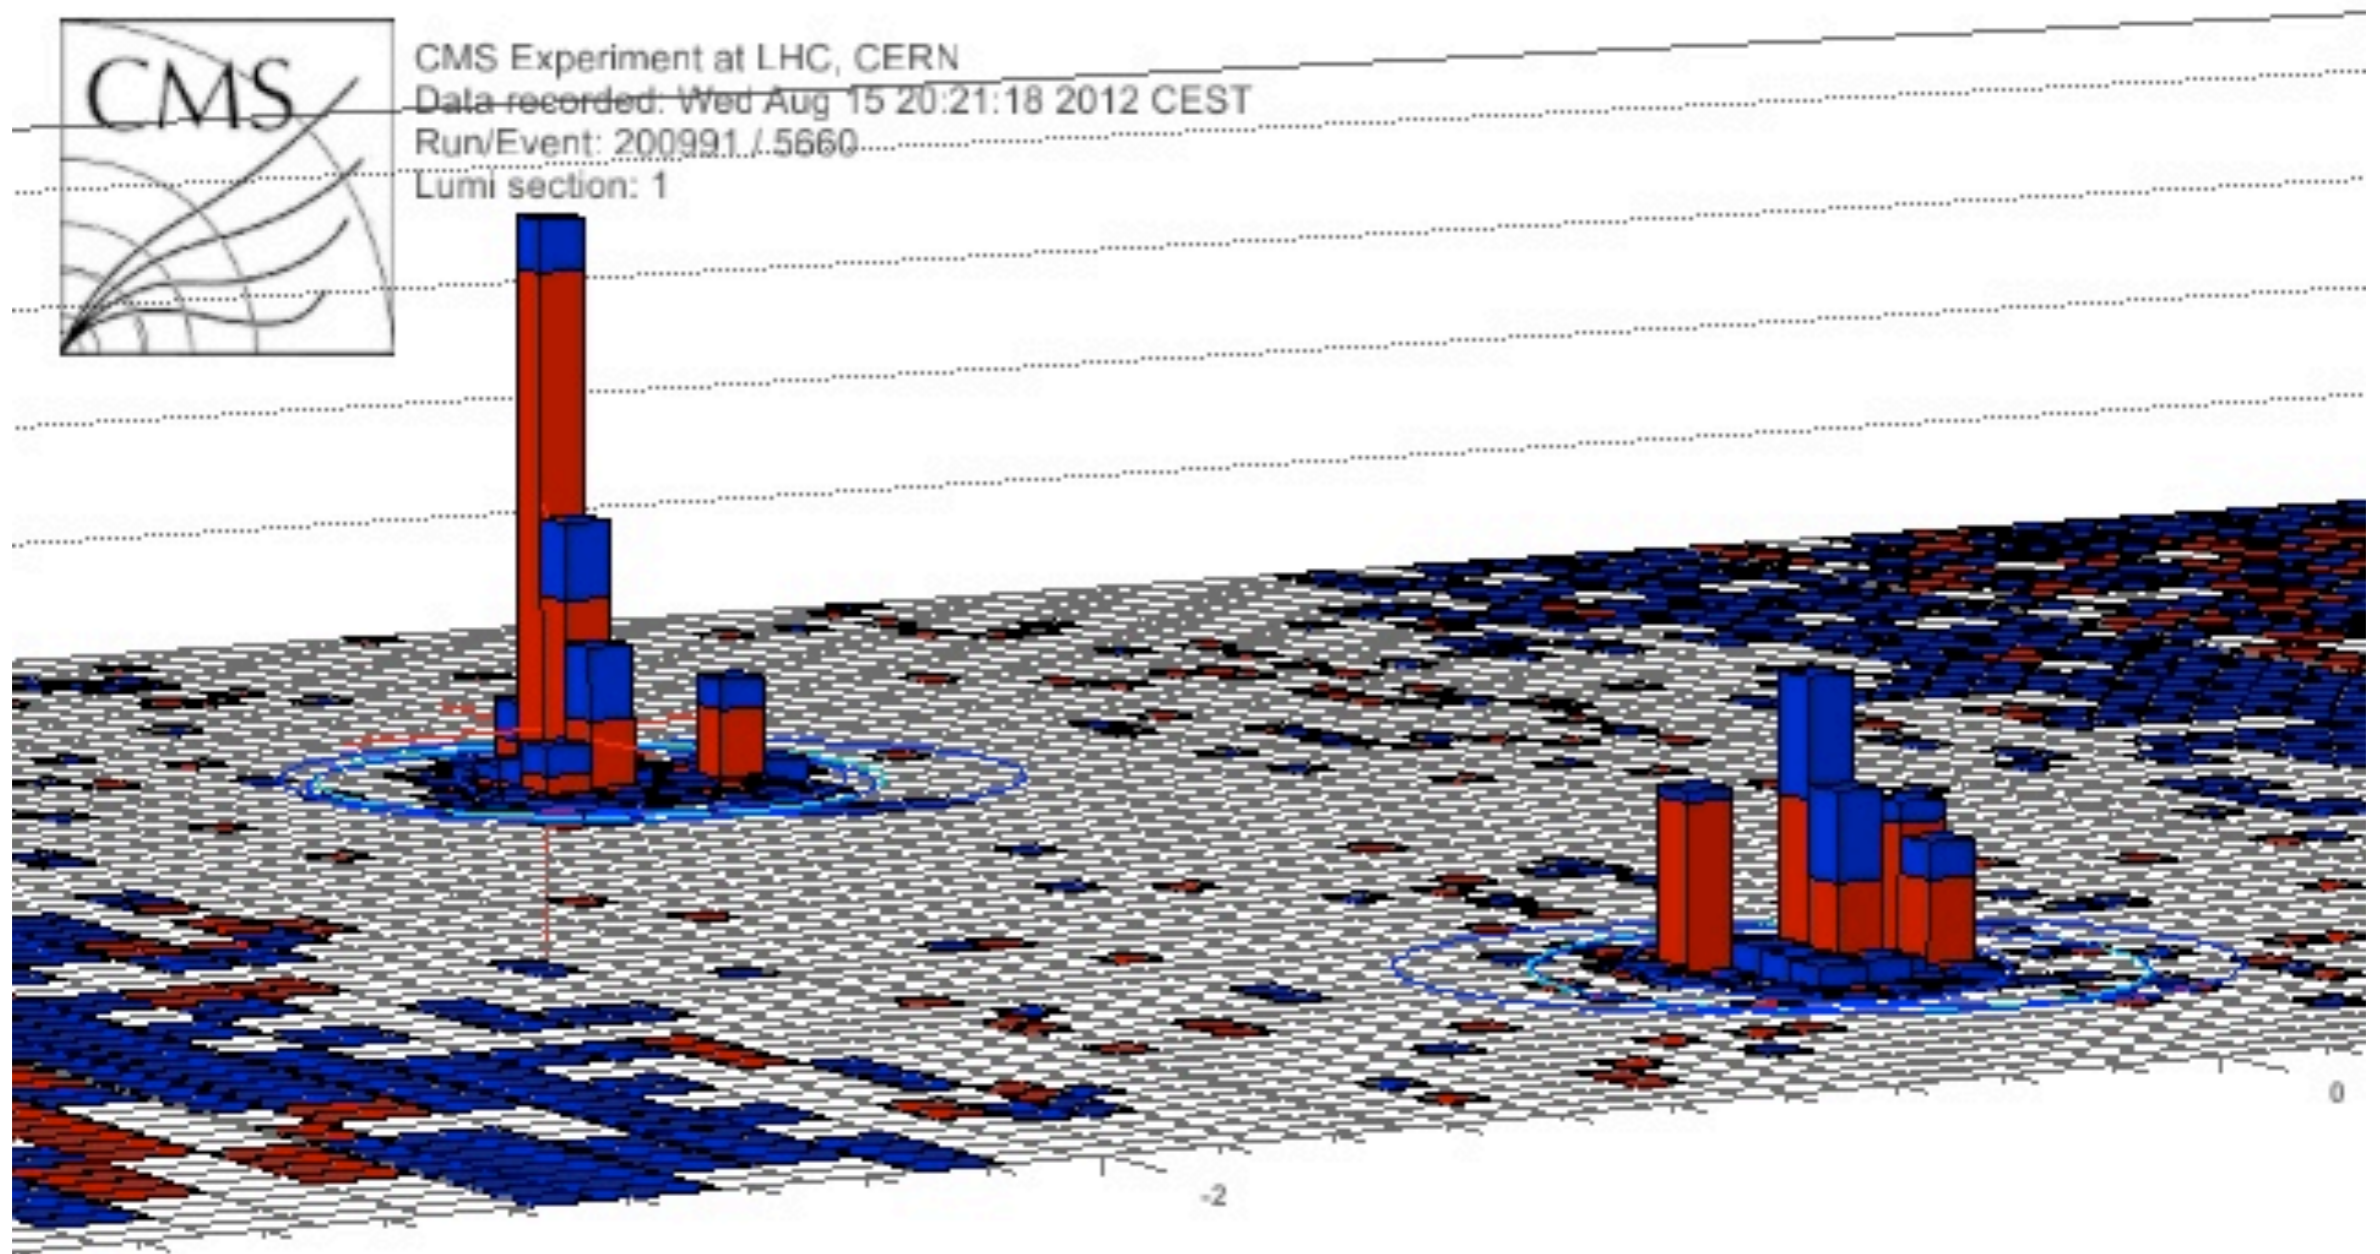

event displays

event displays

two back-to-back top-tagged jets

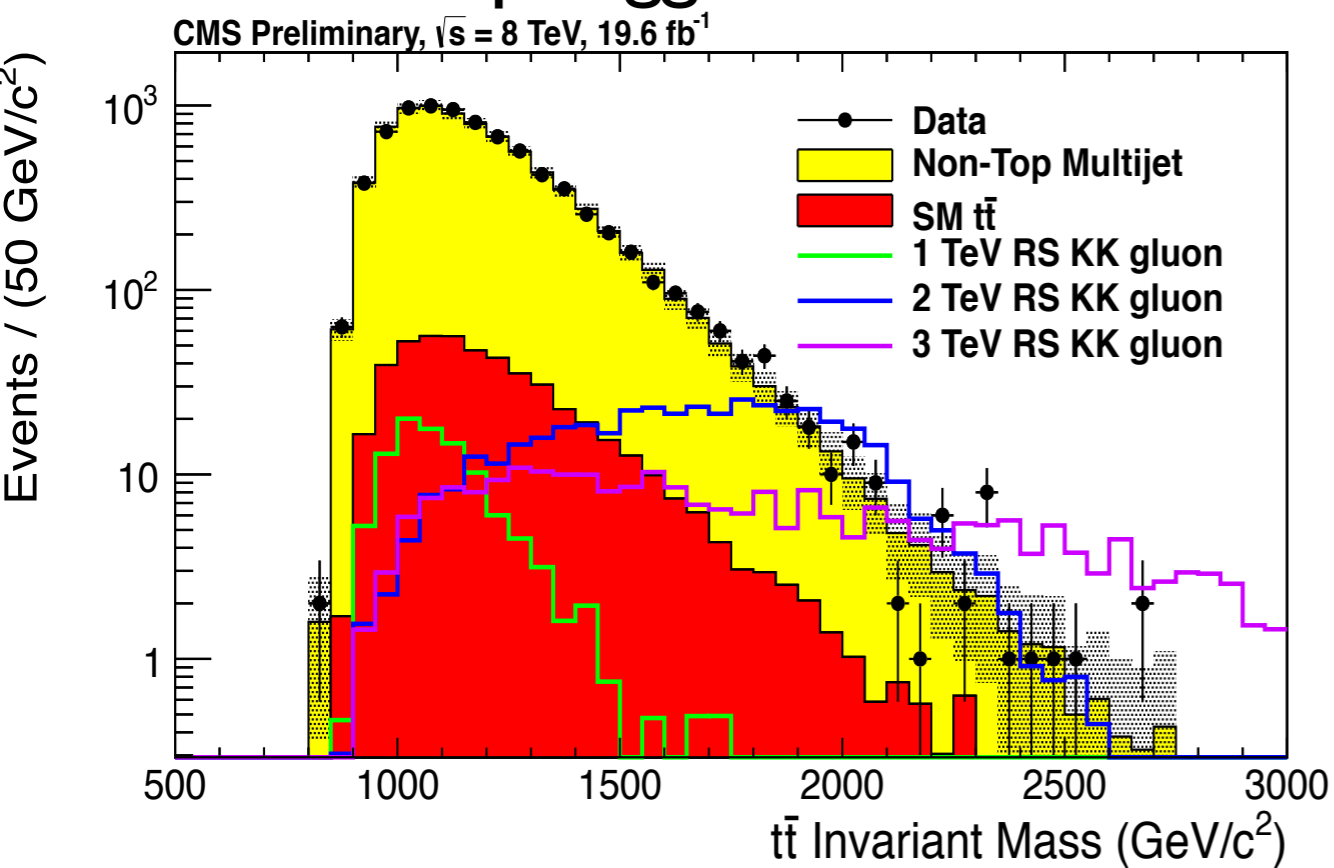

application in analysis

flagship for boosted search for new physics: $t\bar{t}$ resonances

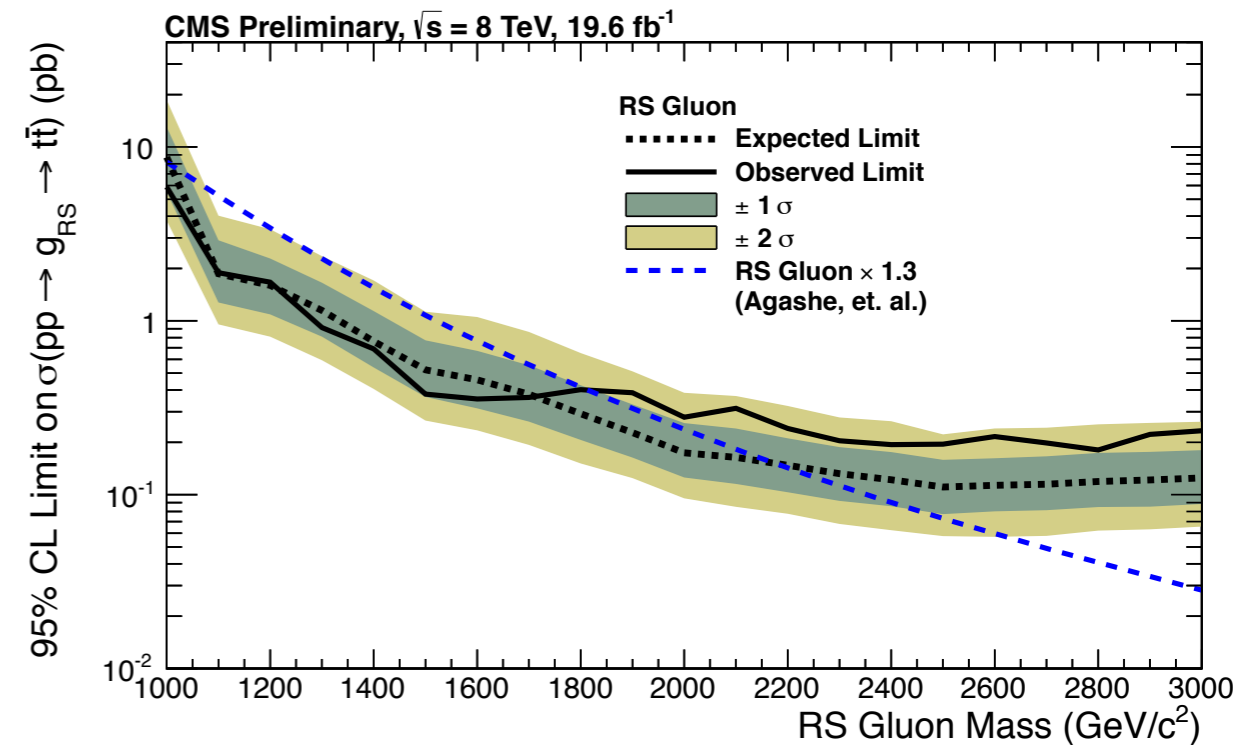

- various models: RS KK gluon, narrow ($\Gamma/m=0.01$) and wide ($\Gamma/m=0.1$) Z' [CMS PAS B2G-12-005]

all hadronic final state:

- two back-to-back jets
- both top-tagged

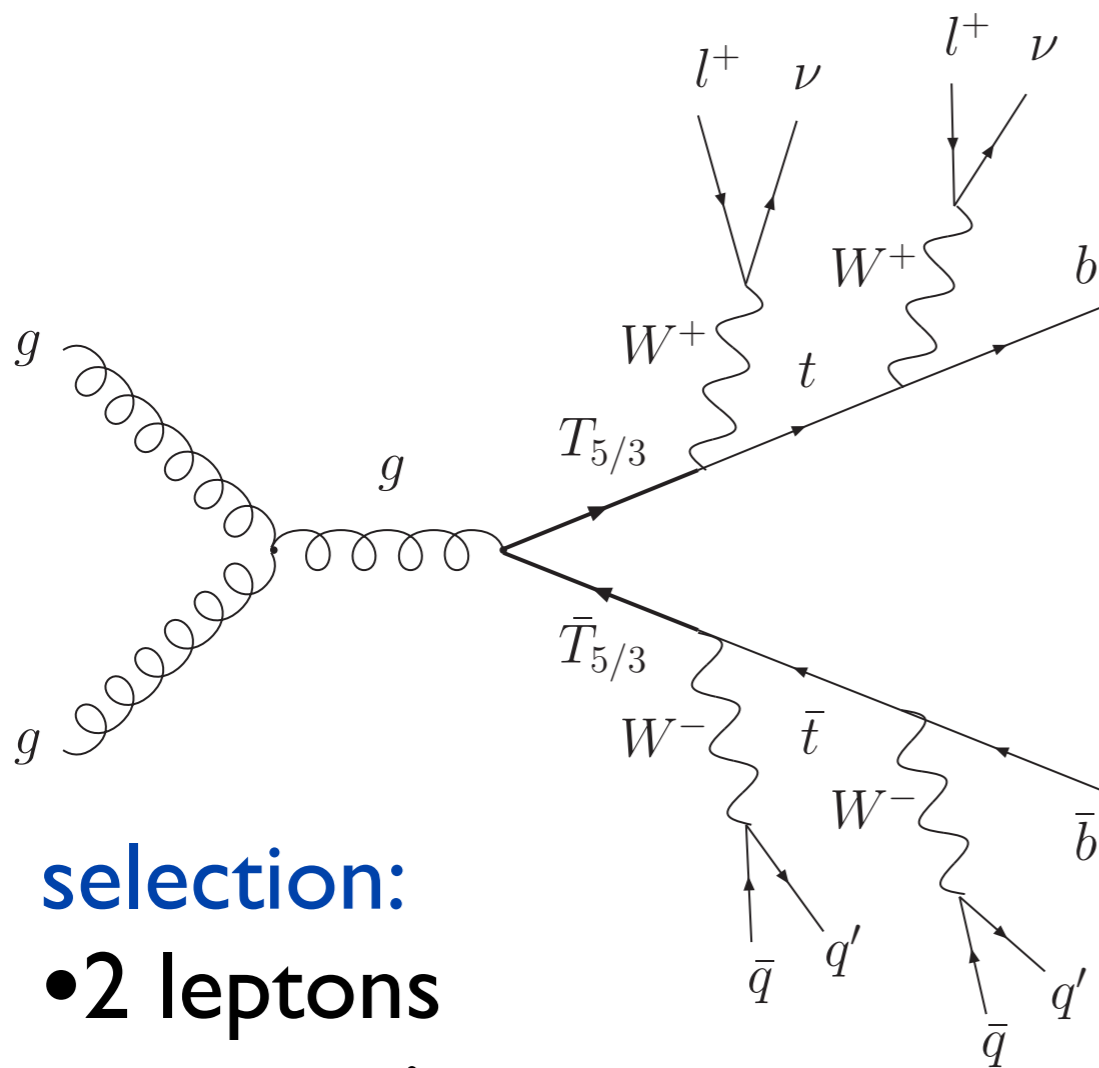

more details: R. Kogler, today 14:30,
session Higgs and new Physics

other search analyses

substructure techniques applied in several BSM searches,
example: top partners with charge $5e/3$ [CMS PAS B2G-12-012]

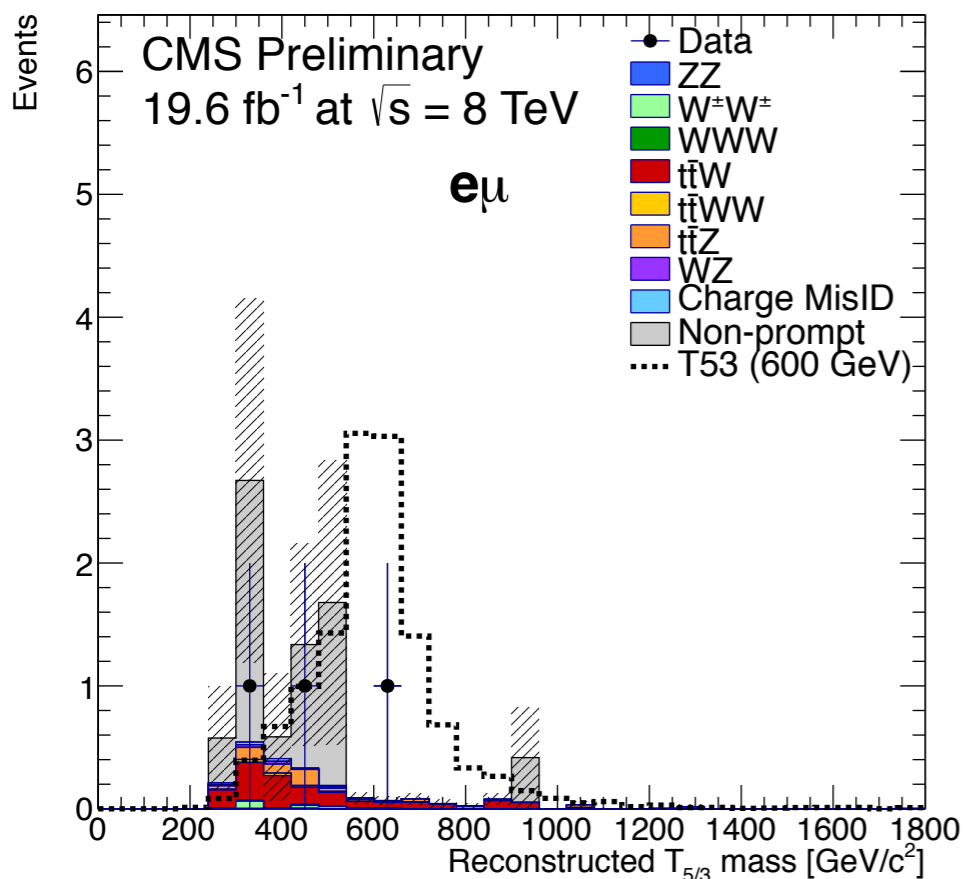

selection:

- 2 leptons
- top-tagging
- W -tagging

results from $T_{5e/3}$ search

- limit calculated from event yield in various channels
- data-derived backgrounds

- limit: expected 830, observed 770 GeV

more details: D. Majumder, today
15:00, session Higgs and new Physics

and more

NEW!

W tagging applied in search for vector-like T' quarks [CMS PAS B2G-12-015]:

- final states with one or more leptons
- soon to come: all-hadronic final state

search for resonances in W/Z tagged dijet mass spectrum

[PLB 5 (2013) 040]:

- resonances decaying into qW, qZ, WW, WZ, ZZ, each decaying hadronic
- **limits:** 2.38 (2.15) TeV for qW (qZ)

CMS preliminary $\sqrt{s} = 8 \text{ TeV}$ 19.6 fb^{-1}

jet mass

study of jet mass as an SM phenomenon [JHEP 05 (2013) 090]:

- verify grooming techniques (reducing UE, PU, soft radiation,...)
- verify modelling of internal jet structure by MC simulations

grooming methods:

- **pruning:** explained in slide 3
- **mass-drop/filtering:**
 - find symmetric splitting by reclustering with CA3
 - new jet defined by 4-vector sum of three hardest subjets
- **trimming:**
 - recluster with k_T algorithm with $R=0.2$
 - accept only subjets with $p_{Tsub} > f_{cut} \lambda_{hard}$ where λ_{hard} is chosen equal to p_{Tjet}

groomed AK7 jet mass compared to PYTHIA in a dijet sample

jet mass

results for pruned AK7 dijets

average jet mass

ratio simulation/data

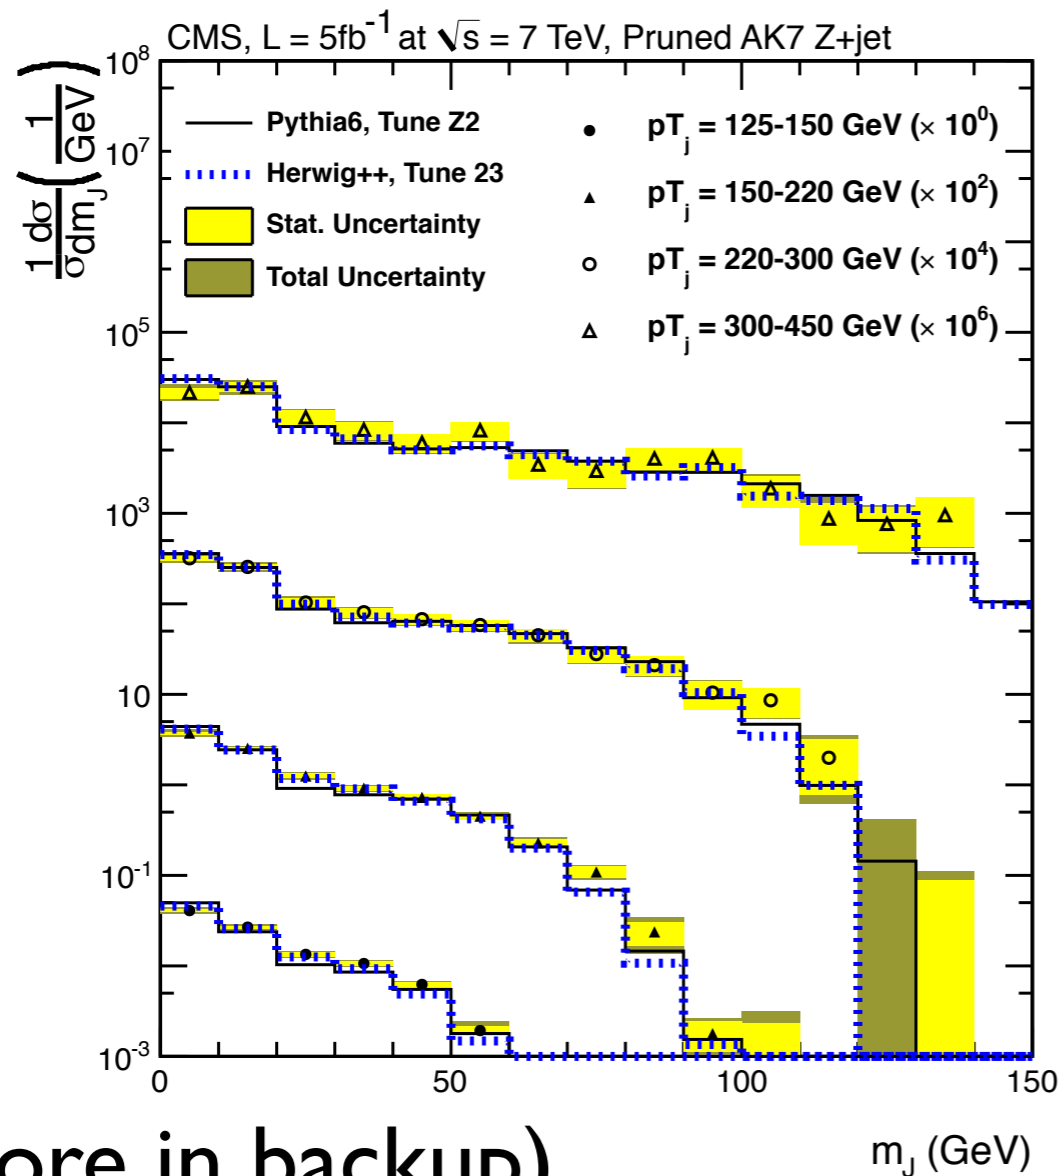

many more distributions (ungroomed, other grooming algorithms etc..) in backup slides

jet mass

results also obtained for V+jets events:

- V+jets preferably initiated from quarks
 - multijets preferably from gluons
- } complementary parton flavor content

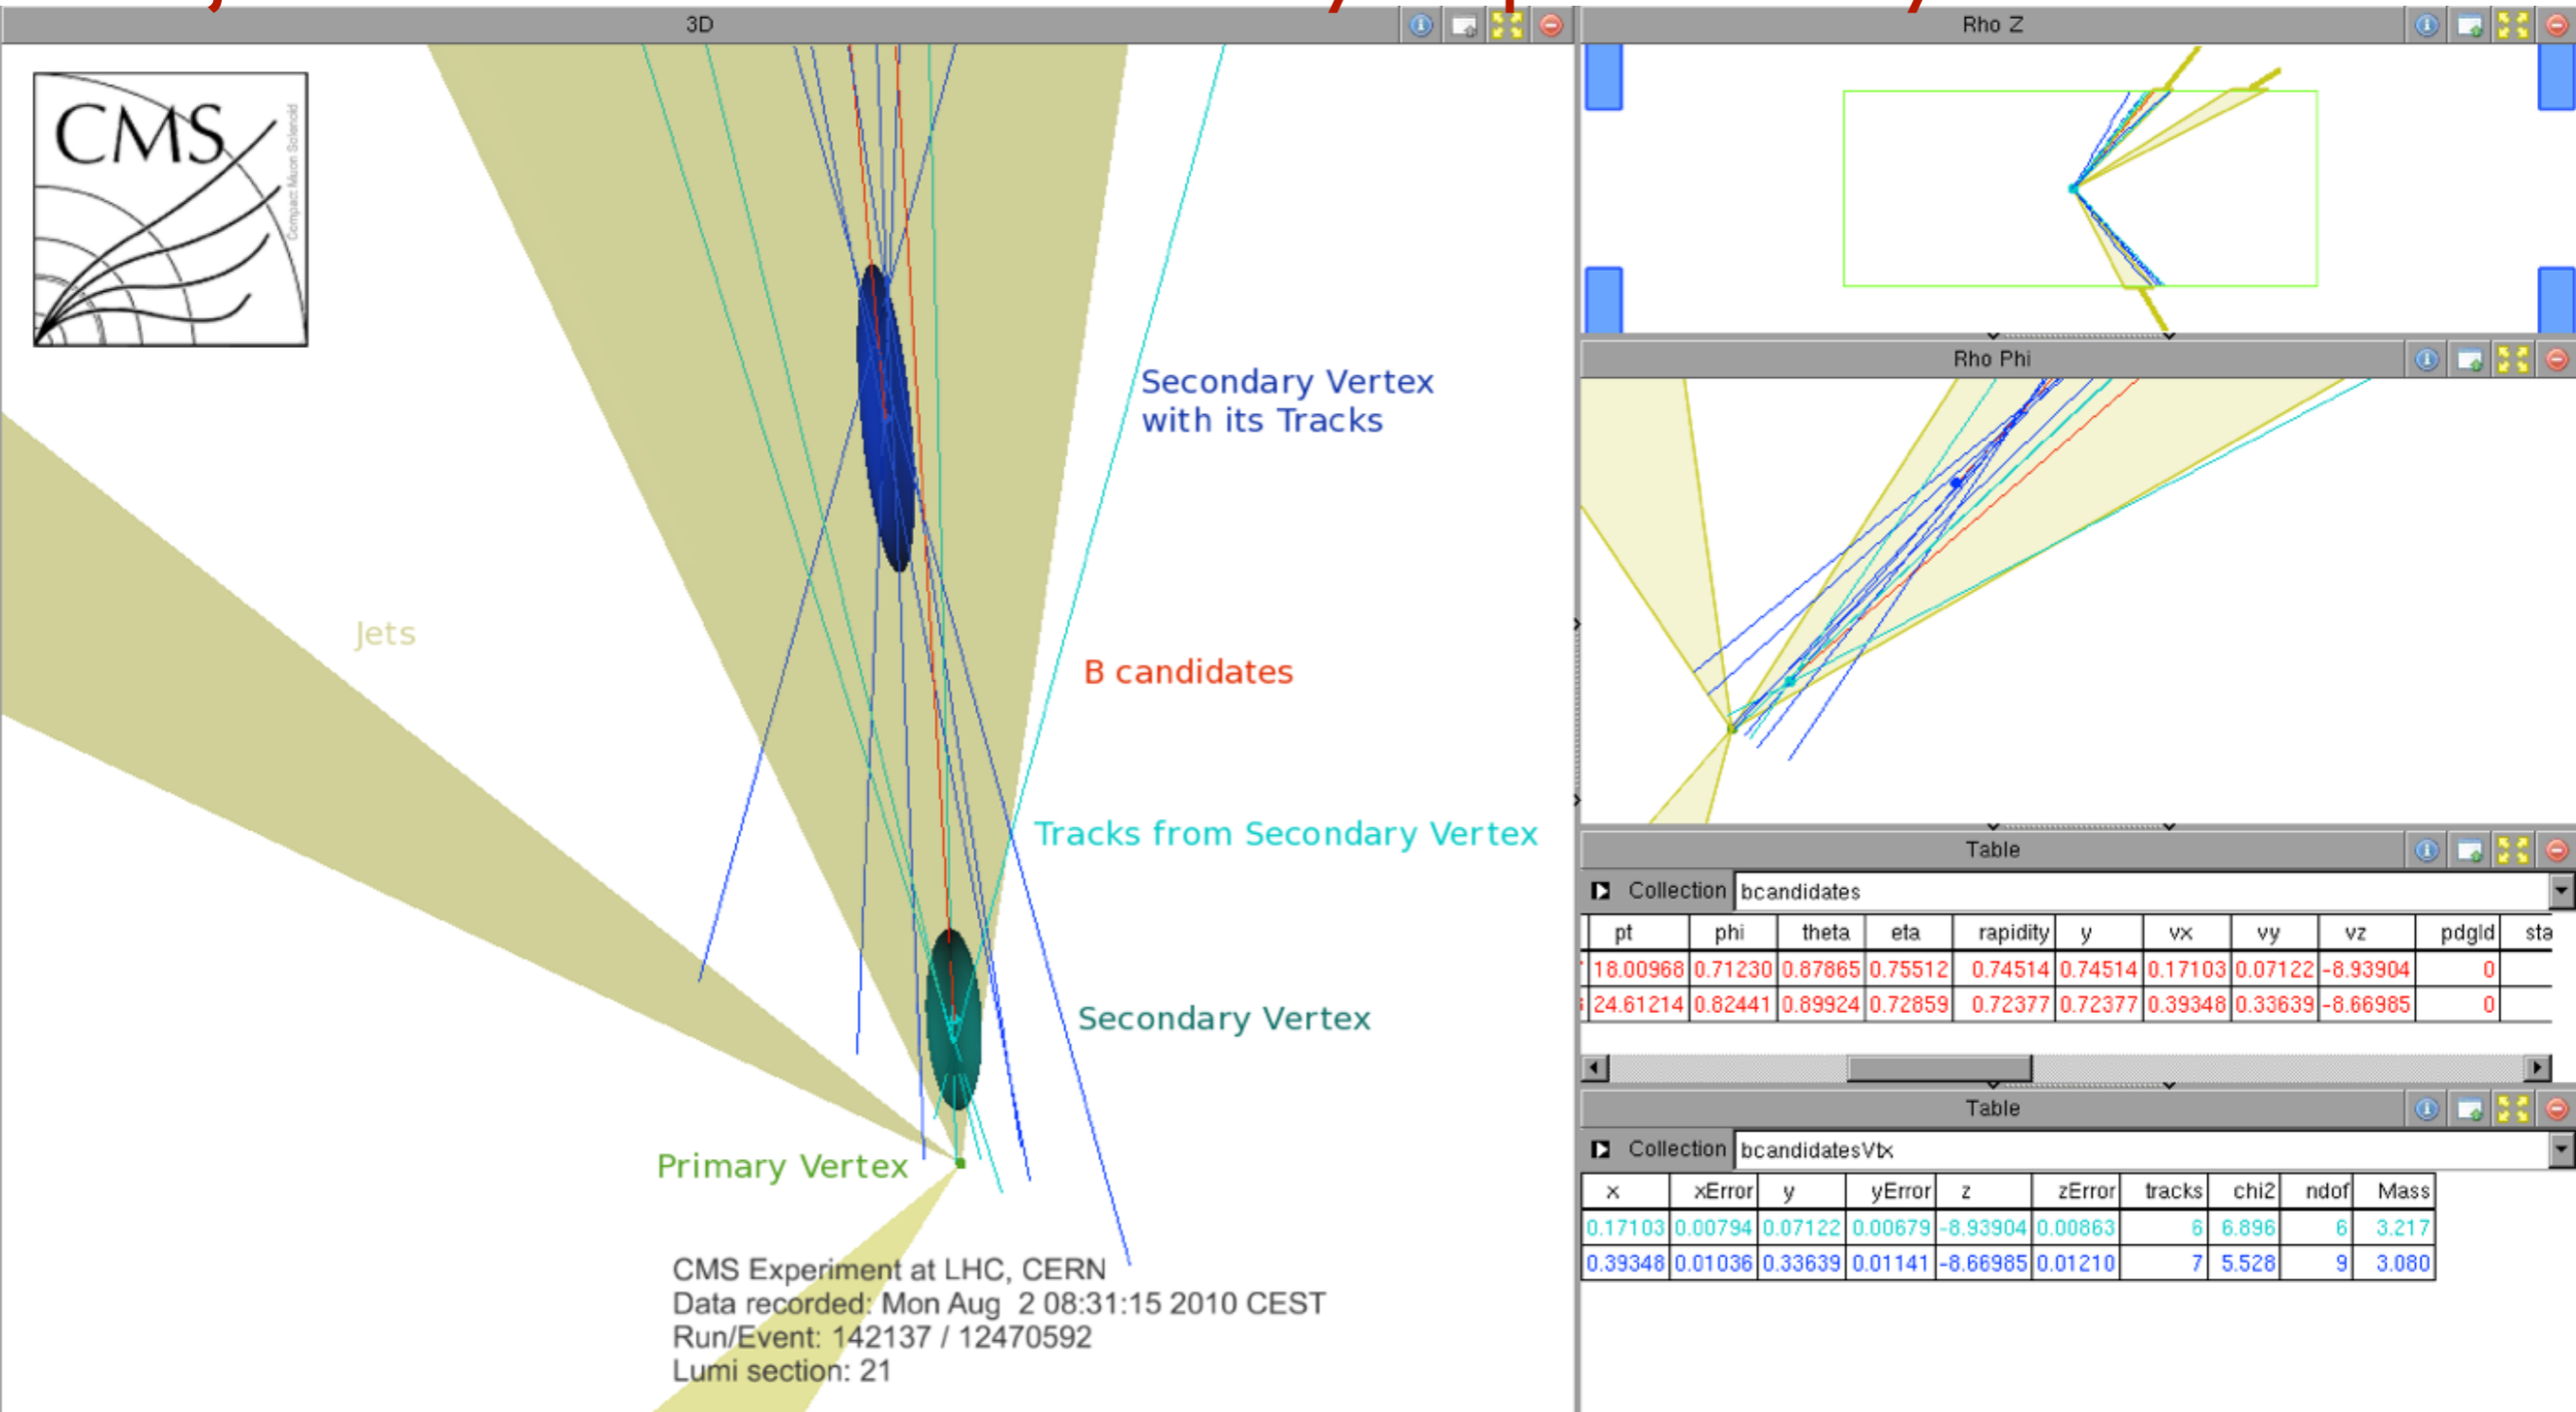

(more in backup)

another dimension

two collinear b-jets with two reconstructed collinear vertices:

➔ jet substructure does not really help to identify this

another dimension

- CMS pioneered an **interesting** new tool:
- **inclusive vertex reconstruction:**
 - ➔ **seeded from tracks** with high impact parameter (**instead of jets**)
 - ➔ **no jets** required
 - ➔ angular resolution is **amazing:**
 $\sigma(\Delta R) = 0.02$
 - ➔ **used to probe b-(jet) production at small angles**

applied in analyses:

- $b\bar{b}$ angular correlations [JHEP 03 (2011) 136]
- $b\bar{b}$ angular correlations in $Z+b\bar{b}$ events [CMS PAS EWK-11-015] (soon to be submitted to journal)

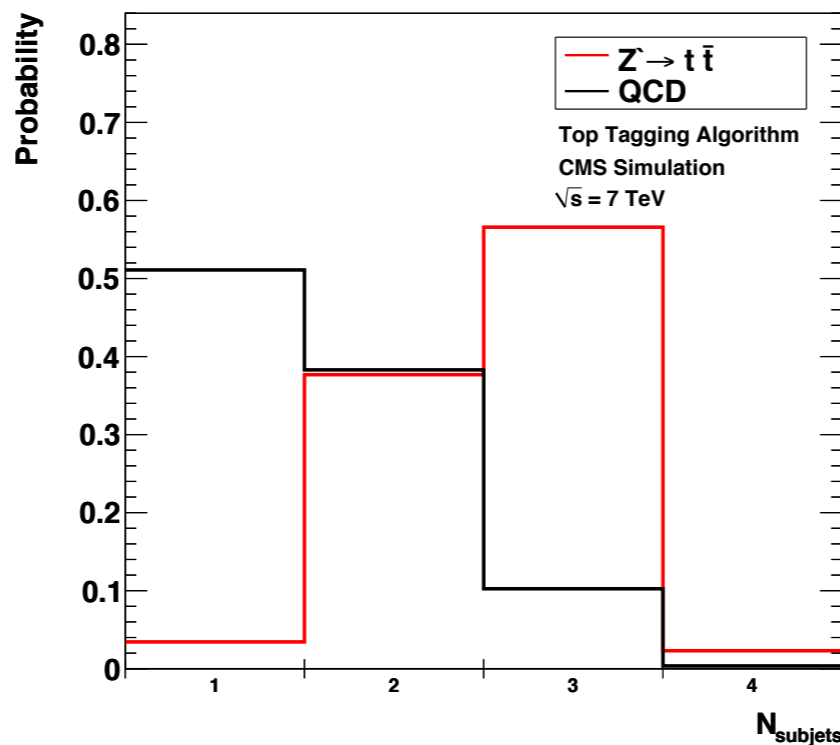

Summary / Outlook

- substructure techniques widely used in CMS
- reasonable description by simulation
- applied not only in typical $Z' \rightarrow t \bar{t}$ search
- lot's of ongoing activity right now
- expect major new results to be released for BOOST 2013 (e.g. b-tagging in subjets, more top-tagging algorithms)
