

Problems for the exam of the JUAS 2012 session on “Synchrotron Radiation”

Physical constants:

dielectricity	$\epsilon_0 = 8.85419 \cdot 10^{-12} \text{ As/Vm}$
velocity of light	$c = 2.997925 \cdot 10^8 \text{ m/s}$
elementary charge	$e = 1.60203 \cdot 10^{-19} \text{ C}$
mass of an electron	$m_e = 9.1081 \cdot 10^{-31} \text{ kg}$ $= 510.974 \text{ keV}$
mass of an proton	$m_p = 1.67236 \cdot 10^{-27} \text{ kg}$ $= 938.211 \text{ MeV}$
Planck’s constant	$h = 6.6252 \cdot 10^{-34} \text{ J s}$ $\hbar = \frac{h}{2\pi} = 1.05443 \cdot 10^{-34} \text{ J s}$

Problem 1 (Short question, no calculation required)

In order to design a modern storage ring for synchrotron radiation a very small beam emittance is required. Describe shortly the most important design criteria to fulfill this requirements. At least 3 criteria should be specified.

Problem 2

- An electron flying through the space with the energy E passes the earth. It is bend by the magnetic field of the earth of $B_{\text{earth}} = 3 \cdot 10^{-5} \text{ T}$ and emits at this time a photon spectrum with a critical wavelength of $\lambda_c = 450 \text{ nm}$ (i.e. blue light). What is the energy E of the electron.
- The electron travels along a trajectory of a total length of $L = 1000 \text{ km}$. How much energy has the electron lost along this passage due to synchrotron radiation? (The influence of the air has to be neglected, assume pure vacuum)

Problem 3

An electron storage ring with the design energy of $E = 3.5 \text{ GeV}$ contains n identical bending magnets with identical beam optics. We assume that all magnets fulfil the Chasman-Green condition. The horizontal emittance is supposed to be $\epsilon_x = 3 \cdot 10^{-9} \text{ m rad}$.

- How many bending magnets are at least required in the lattice?
- How long are the bending magnets (i.e. the length of the trajectory in the magnet), if the field strength is $B = 1.5 \text{ T}$?

Problem 4

A linac provides an electron beam with very small transverse dimensions. The beam energy is $E_b = 100 \text{ MeV}$. Behind the linac a permanent magnet undulator with a periode length of $\lambda_u = 15 \text{ mm}$ is installed. The pole tip field is $B = 0.9 \text{ T}$. This undulator produces a coherent radiation with a wavelength of $\lambda = 290 \text{ nm}$.

- Calculate the required gap height of the undulator.
- How long is the magnet in order to get a line width of $\Delta\lambda/\lambda = 5 \cdot 10^{-3}$?

GOOD LUCK !
