

High Precision Spectrometers (HPS) to add to CMS

for very forward protons
Forward Physics at LHC February 2013

Michael Albrow, Fermilab
(on behalf of many HPS collaborators)

Prehistory

History

Overview

Physics at Stage 1 (and a little Stage 2)

Optics and acceptance

Tracking

Fast Timing detectors and reference time

Summary of situation

Exclusive Central Production: $p + p \rightarrow p + X + p$

Some $p + X$ studies also

Special high mass exclusive channels for LHC:

- Double “pomeron” interactions: $IP + IP$ (or $g+g$ [g]) $\rightarrow X$, e.g. $X = \mathbf{Higgs, JJ}$
- Photoproduction: $\gamma + IP$ (gg) $\rightarrow X$, e.g. $X = \mathbf{Z}$
- QED & Electroweak $\gamma + \gamma \rightarrow X$, e.g. $X = \mathbf{W^+W^-}$

At Tevatron in CDF we have observed: $X = e+e-, \mu+\mu-, J/\psi, \psi(2S), \chi_{c0}, \gamma\gamma, JJ$

At LHC more results come (this workshop)

& $f_0(980), f_2(1270), f_0(1370), X?$

Personal reminiscence: ISR R806 → R807: Axial Field Spectrometer

p + p at $\sqrt{s} = 63 \text{ GeV}$

Homage to Bill Willis

1932-2012

- 1st liquid argon calorimeter
- 1st transition radiation e/ π separation
- 1st Uranium hadron calorimeter
- Full azimuth drift "jet" chamber

+Radeka
+ Palmer

1982: Co-discovery with UA2
of high- E_T jets in hadron-hadron collisions
← **on-line** event display (hits) : ~ **exclusive dijet??**

Deja vu:

AFS designed for high E_T , but we added forward proton trackers for p + X + p (double pomeron)

Axial Field Spectrometer

On-line event display selecting $\Sigma ET > 25 \text{ GeV} / 63 \text{ GeV}$ vs (pp) ISR

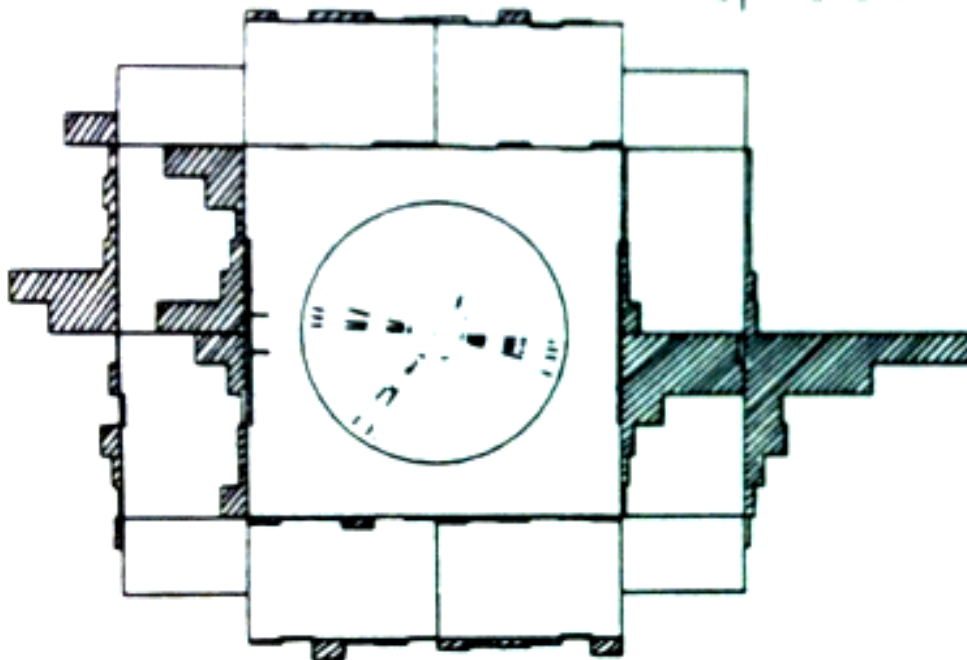

> 30 years ago!

AFS -EVENT DISPLAY- 7-OCT-82

All wire hits shown (all)

TRANSVERSE

$E_T > 27 \text{ GeV}$

We had very forward proton tracking both sides at large $|\eta|$...

Did not interrogate for these events! Low- β quadrupoles for $\xi(p)$ (1st in collider) but off.

Added forward p-tracking to Axial Field Spectrometer for DPE: $p + X + p$. "Central Exclusive Production" Maybe $X = G = \text{glueball}$?

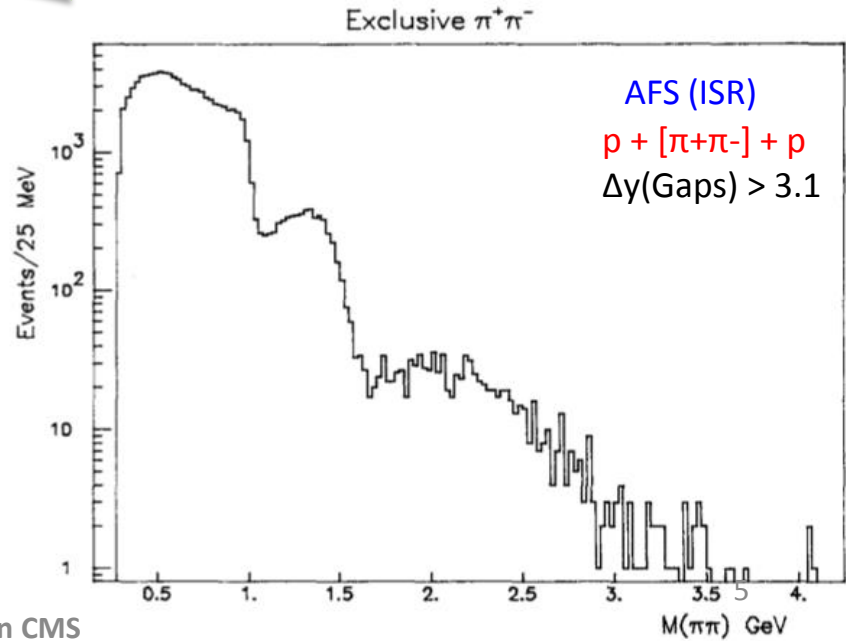

A SEARCH FOR GLUEBALLS AND A STUDY OF DOUBLE
 POMERON EXCHANGE AT THE CERN INTERSECTING
 STORAGE RINGS

(The Axial Field Spectrometer Collaboration)

12 such drift chambers,
 4 wires with Q-div (2mm)

90,000 $p\text{-}G\text{-}\pi^+\pi^-\text{-}G\text{-}p$ events with
 gaps G with $\Delta y > 3.1$.
 $f_0(980, 1370)$ $f_2(1270)$ & ...???
 (Now have at CDF 900 & 1960 GeV)

Looked for vacuum excitation of scalar glueballs, G
 That search continues at Tevatron (CDF) and LHC.
 Next:

Look for vacuum excitation of scalar Higgs, H

Both are scalars $J^{PC} = 0^{++}$

AFP/HPS for p + H + p : Long History

March 2001: MGA et al., Lol to Fermilab PAC :

"A search for the Higgs boson using very forward tracking detectors with CDF"

Later posted: hep-ex/0511057 Silicon tracking, Roman pots, $z = +/- 55m$

Novel: Missing mass $M(pp)$ [MGA+ Andrei Rostvtsev, hep-ph/0009336]

Timing for $z(pp)$ & pile-up rejection, Quartz Cherenkov hodoscope. $p + \gamma\gamma + p$

Durham Theorists Khoze et al: Signal small but backgrounds v small too ($JJ = gg$)

Huge uncertainty in $\sigma(H \sim 120 \text{ GeV})$ from 0.06 fb (KMR Durham) to $\sim 100 \text{ fb}$!

CDF program to measure exclusive $\gamma\gamma, \chi c$, Jet+Jet to test theory. (Durham wins)

Dec 2003 (- 2010): First of 8 "Manchester Christmas Meetings"

Organizing committee

Brian Cox (Manchester)

Jeff Forshaw (Manchester)

Valery Khoze (Durham)

Robin Marshall (Manchester)

James Stirling (Durham)

Cinzia Da Via (Brunell)

Alber De Roeck (CERN)

MANCHESTER
1824

Forward Physics At The LHC

→ FP420 : Forward protons at 420 m
Higgs on the menu

May 2004, Fermilab workshop on Future QCD at Tevatron... GTeV (died with BTeV)

~ 2008/9 ATLAS concentrates on AFP and CMS on HPS (continue sharing R&D)

ATLAS and CMS have now found a “Higgs-like particle” at 125 GeV

Is it a Standard Model Higgs, or BSM Higgs or something else?

Now LHC has a > 10 year program to measure all its properties:

Branching fractions and couplings, production mechanisms, spin, CP, width etc.

OBVIOUSLY : We should measure it every way we can.

We propose a different, complementary way:

CENTRAL EXCLUSIVE PRODUCTION: $p + p \rightarrow p + H + p$

CP must be ++ Determination in ZZ^* assumes CP conserved (Tx VK)

Suppose (Gunion inter alia) in NMSSM H(125) is heavier one

and $h'(98 \text{ GeV}) \rightarrow b + \bar{b} / \tau + \bar{\tau}$ Hard to see inclusively

Belanger et al. arXiv:1210.1976 (2013)

Higgs Bosons at 98 and 125 GeV at LEP and the LHC

Spin must be $J = 0$ or 2 , and we can distinguish the

Coupling to gluons via q -loop

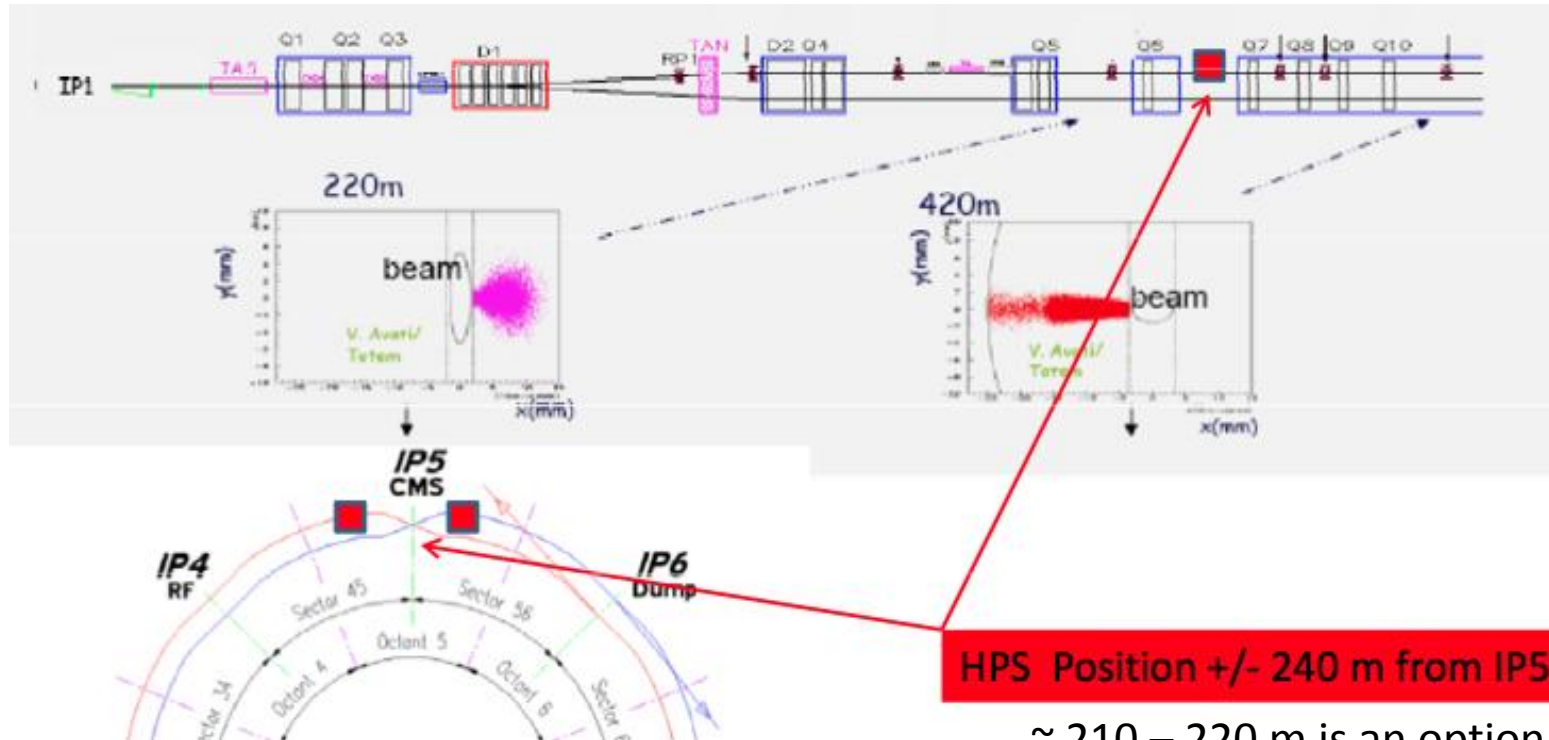

(May want exclusive $\gamma\gamma$ to calibrate σ)

Mass ($\sigma(M) \sim 2 \text{ GeV}$ per event, Missing Mass to protons, and can calibrate that),

Needs proton detectors
at $z = \pm 420 \text{ m}$ (later)

HPS: High Precision Spectrometer @ CMS

Detectors to measure leading protons, tracks for momenta and timing for pile-up rejection. (ATLAS has equivalent ATLAS Fwd Protons)
Designed for $L = 10^{34}$ with ~ 30 ints/X. Read out for every CMS recorded event

HPS Position +/- 240 m from IP5

~ 210 – 220 m is an option
(interleaved/with TOTEM)

HPS will have two pairs of stations:

- 1) At $z = +/- 240\text{m}$,
to install in LS1 or 2015, data in 2015/6
- 2) At $z = +/- 420\text{m}$ (2016-18?) → needed to see H(125)

We are working on phase I, the detectors at +/- 240 m. L1 trigger just in reach.

At 240 m (& 220 m) the beam pipe is exposed, so it's relatively easy to install the detectors:

At 420 m missing magnet, pipe straight but cold. It requires a cryogenic by-pass

Looking downstream (CMS behind you)

Physics for Stage 1:

Both protons measured, $M(\text{min}) \sim 200 \text{ GeV}$:

Exclusive dijets, $M(\text{JJ})$ to $\sim 750\text{-}1000 \text{ GeV}$. Pure g-jets
< 1% b-bbar dijets (need double b-tag). Test of $J_z = 0$ rule. (Khoze, Martin, Ryskin)
(q-qbar dijets forbidden for massless quarks at $t = 0$.)

Test of pQCD mechanisms of exclusive production, “superhard” pomeron.
Unintegrated $g_1 g_2(x_1, x_2, Q^2)$, Sudakov form factor, gap survival probability, etc.
Measure exclusive bJ-bJ spectrum (important for later).

Measure $\gamma\gamma \rightarrow W+W-$. Anomalies in WW final state interactions (but transverse, so H would not appear in $\gamma\gamma$). Triple, quartic gauge boson couplings:
more sensitive than standard techniques (C.Royon et al.)

BSMH not fully excluded in $M \sim 200 - 600 \text{ GeV}$.
May be visible in $\tau^+\tau^-$ channel e.g.
Other exotic heavy states with “vacuum” Q.Nos & $J = 0, 2$
coupling (even indirectly like H) to gg.

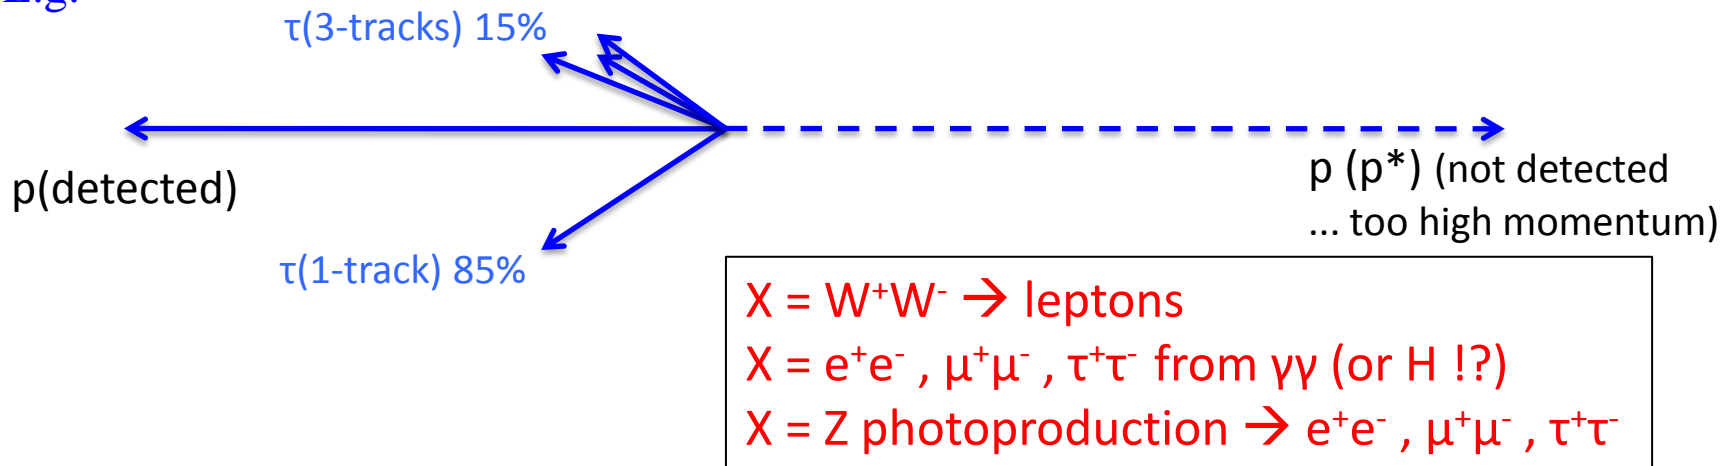

One proton measured, still some physics at high PU?:

High mass diffraction well explored in ~ 1 week of $\mu = \langle n/x \rangle \sim 1$ running $\sim 100/\text{pb}$.

$M(\text{min}) \sim 100 \text{ GeV}$.

No $M(X)$ from p 's, no PH rejection by timing, but very clean central states may be accessible.

E.g.

No additional tracks on X vertex (already very selective)

In $e^+e^-, \mu^+\mu^-, \tau^+\tau^-$ cases $\Delta\phi = \pi$ and $\mathbf{p}_T(X) \sim \mathbf{0}$.

Can we see $p + [\text{H125} \rightarrow \tau^+\tau^-] + p^*(\text{undetected})$ in Stage 1 ??

(Study with Harland-Lang, Khoze, Ryskin)

3-momentum of X ($\sim p_z$) determines both proton momenta

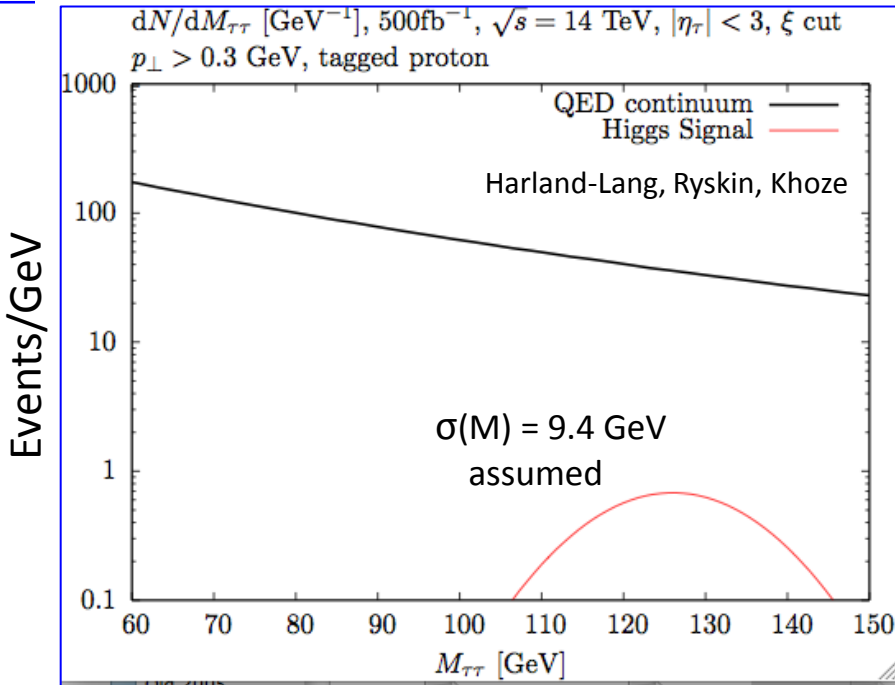

$e^+e^-, \mu^+\mu^-$ already calibrates HPS spectrometers (don't need both p 's)

Can we see H(125) in Stage 1 with one proton?

Exclusive $p + \tau^+\tau^- + p$ (clean) :

Only 3 sources:

- 1) QED: $\gamma\gamma \rightarrow \tau^+\tau^-$
 - 2) Photoproduction: $\gamma+IP \rightarrow Z$ (BR = 3.7%)
 - 3) Gluon fusion $IP + IP \rightarrow H$ (BR = 6%)
- 1st two same in e+e- and $\mu^+\mu^-$ (control)

Two neutrinos missing, but 4-momentum constraints & two $M(\tau)$ constraints.

a) If fully optimised, how good can $M(\tau^+\tau^-)$ be?

Factor x2 better $\sigma(M) \rightarrow$ factor x2 peak height and in S:B. (possible??)

b) QED continuum, $\gamma\gamma \rightarrow \tau^+\tau^-$, $p_T(p) < p_T(p)$ in $H \rightarrow \tau^+\tau^-$ (gluons, or IP)

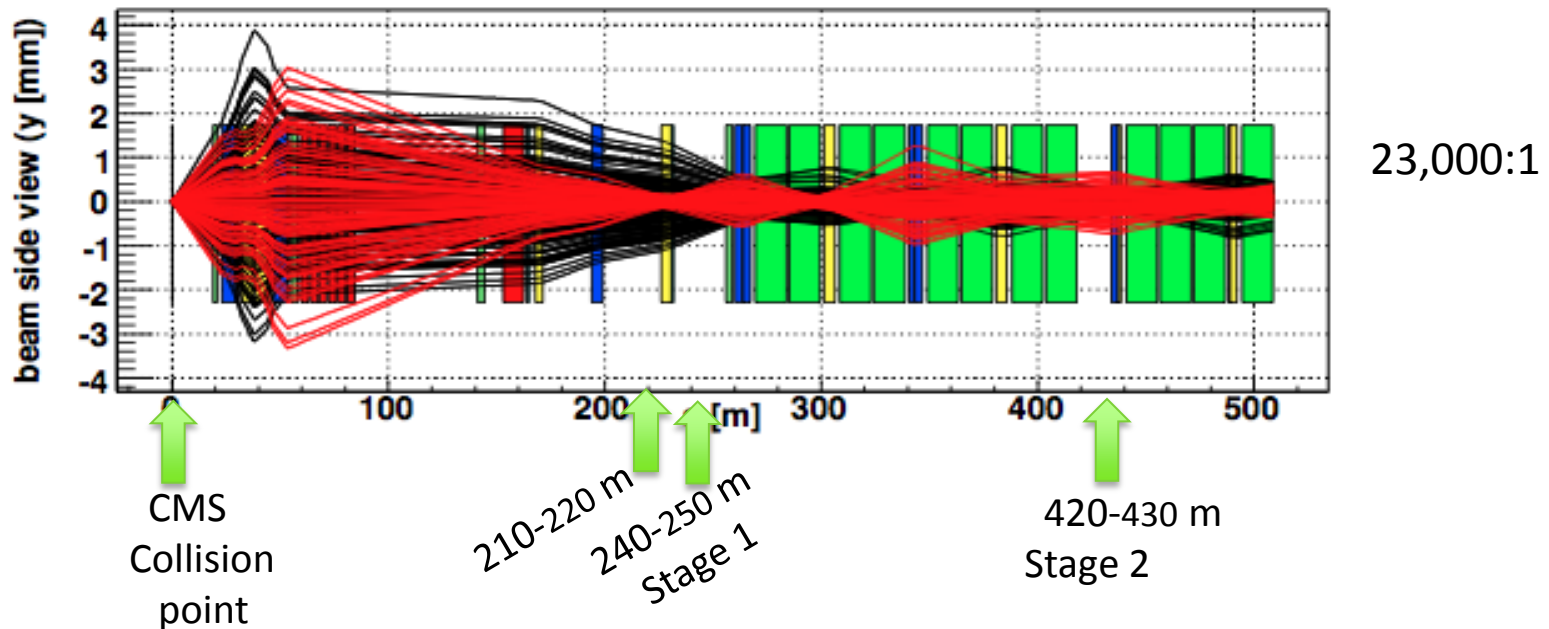

$p_T > 0.3$ GeV cut (as in plot) reduces QED by factor ~ 5 , only 10% reduction in H.

c) Unseen low mass p-dissociation on other side increases σ , factor ~ 2 (?) without spoiling kinematics. $\sigma(H)$ also uncertain by a factor $\sim 2-3$ each way.

Still, SMH(125) $\rightarrow p + \tau^+\tau^- + p^*$ probably too small to see in Stage 1.

>> at Stage 2 with 420+240 have other p, better mass resolution, & timing for z(vtx) constraint. :-)

Several tracking programs have been used (HECTOR, FPTrack).
Full transport line simulation in CMSSW.

Machine optics LHCB1(2)IR5_v6.500.tfs for Beam 1(2)

Private particle gun (t, ξ, ϕ) based on HECTOR at $\sqrt{s} = 14$ TeV

Single arm acceptance in t, ξ

15mm x 12mm detector (QUARTIC) at 2 mm from beam

$\xi = 0.02, \Delta p_z \sim 150$ GeV

t, ξ contours in x, y plane at $\pm 240\text{m}$

For any $|t|$ up to 4 GeV^2 and ξ $0.01 - 0.1$ see fraction of azimuth ϕ accepted, hence $A(t, \xi)$
Can see effect if $\Delta x = 2\text{mm} \rightarrow 3\text{mm}$ e.g. 15mm in x not bad unless $\xi > 0.1$ is important.
Note: All small t (Photon exchange) near $y = 0$.

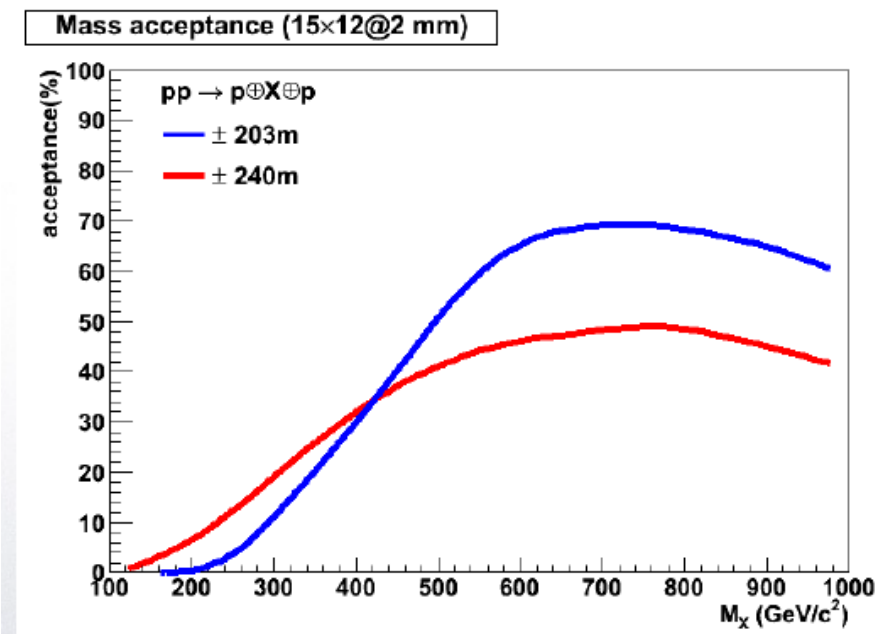

Z = 240m (CMS ref. frame)

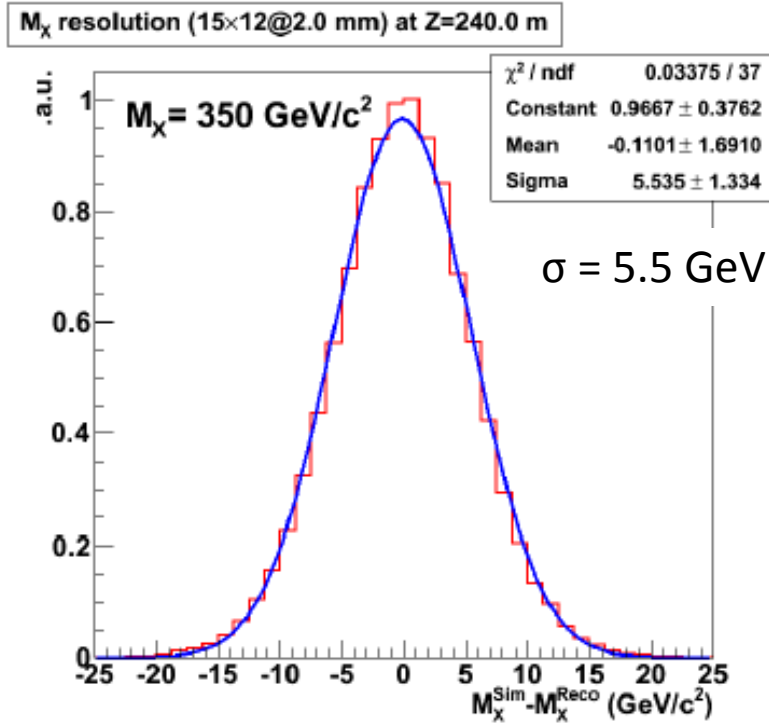

Z = -240m (CMS ref. frame)

Mass acceptance differences before (203m) and after (240m) Q6
 Assuming $\Delta x = 2\text{mm}$ at both locations.

More W+W- events < 350 GeV, but similar total numbers
 Closer to H(125) for $b\bar{b}$:gg ratio and $J_z = 0$ tests

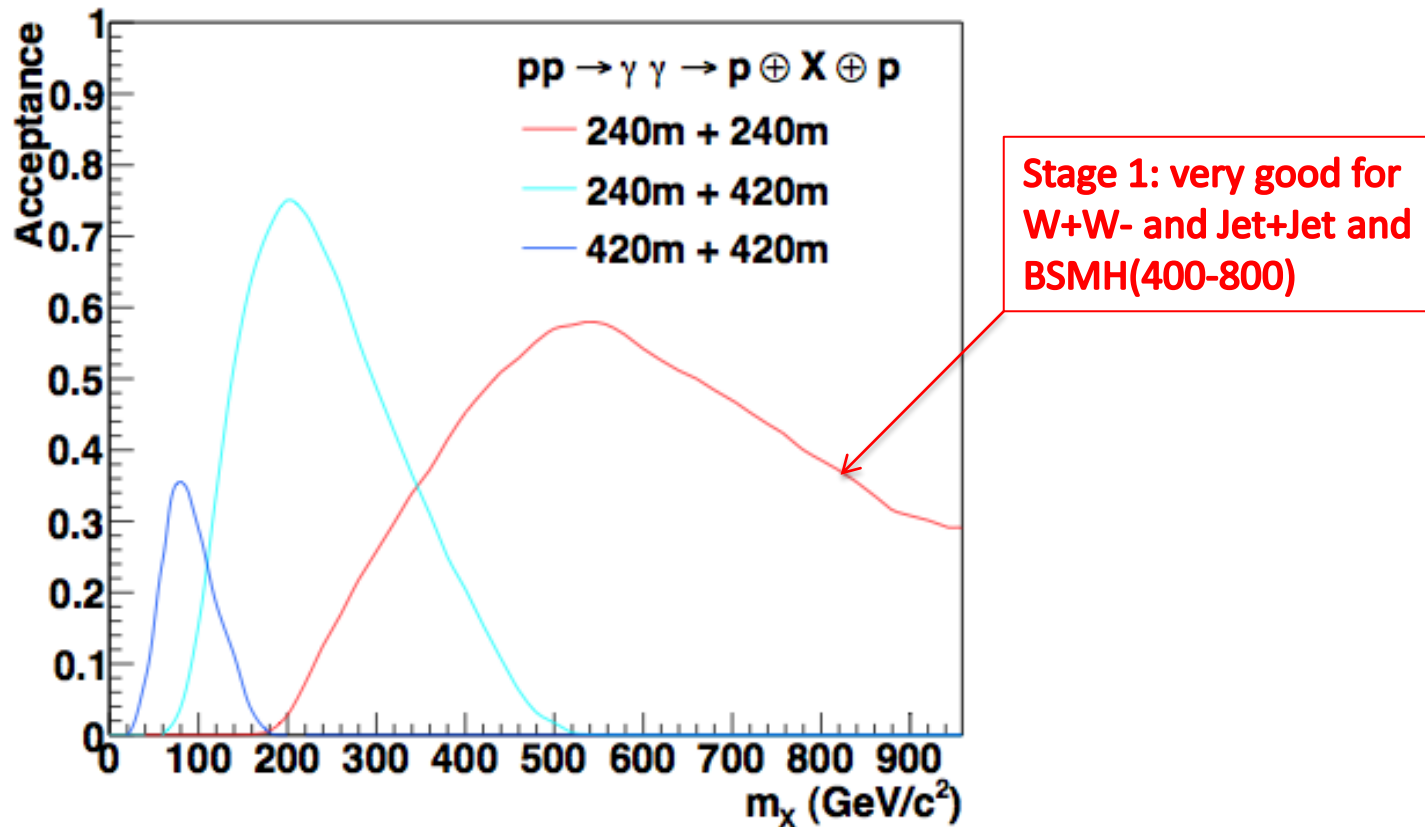

Simulation of mass resolution with
 240 + 240 m with full smearing.
 Assumes 10 μm x-resolution and
 1 μrad angular resolution

Mass acceptance for two arms for small $|t|$ at Stations 1 & 2

(Assumes $\Delta x(\text{min})$ from beam = 3 mm at 240m)

Each arm at 240m by itself has \sim superimposed light blue and red.
Stage 2 has \sim all 3 superimposed, and light blue x 2.

For IP + IP $|t|$ is larger and acceptance shifts.

For H(125) best is [240 + 420] & [420 + 240]

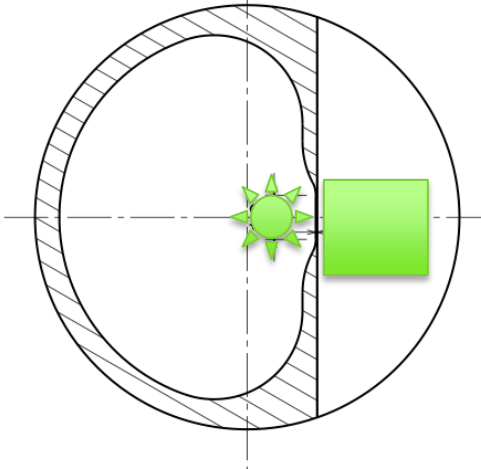

For NMSSM $h_1(98)$ 420+420 is better

Moving pipe mechanics – “Hamburg” moving beam pipe

Long pockets 30 – 40 cm for long detectors (Tracking + timing + extra).

No atmosphere-vacuum forces, easily accessible.

Only developed solution for Stage 2 at 420 m.

Domenico Dattola (INFN)

Mike Albrow HPS in CMS

HPS has 2 main components: tracking and timing:

A tracking detector (silicon pixels – perhaps 3D) to measure

→ Position and angle, combined with the beam magnets, allow to determine the momentum of the scattered proton and in turn the missing mass (from both p's)

Two pockets ~ 8 - 10 meters apart:

Momentum reconstruction: $\Delta p/p \sim 2 \cdot 10^{-4}$ (at 420m: 120m of 8T dipoles)

→ Position precision of 10 μm

→ Angular resolution of 1-2 μrad

Need precision track detectors (~ 10 $\mu\text{m}/\text{stack}$), Rad Hard, edgeless (on one side) but small: ~ 2 cm^2 per layer, ~ 6 + 6 layers per arm.

Can be same but $< \sim 10^{-3}$ of CMS Central tracker upgrade

Good first use! + space for innovative tracking (diamond e.g.) or timing devices

Working with CMS tracking experts (especially pixel upgrades, Simon Kwan et al)

Cooperation with several manufactures and with ATLAS

TRACKING (no details here)

Front and back stations, each with a 6-plane stack $\sim 32 \times 16 \text{ mm}^2$
PSI46 ROCs read 80×52 pixels each $100 \times 150 \mu\text{m}^2$

Use CMS Central tracker upgrade detectors (and some of the people!)

Silicon : 3D pixels tested among others CNM/D+T Microelectronica (Barcelona)
or slim-edge (0.2 – 0.3 mm) planar pixels e.g. VTT (Finland) and SINTEF (Norway)

Tests in Fermilab test beam of several CNM and FBK 3D sensors,
different electrode spacings and sensor thicknesses.

Irradiation at Los Alamos to 10^{15} neq/cm^2 under evaluation

Further tests in Summer at Fermilab (possibly combined with QUARTIC module)

Timing detectors, to measure the vertex position to reject Pile-Up.

Timing measurement (Cherenkovs) from both sides of CMS allows to determine the vertex of the protons and reject pile-up (proton from different pile-up collisions)

Time resolution ~ 10 ps

Vertex z-by-timing: ~ 2 mm

Segmentation for > 1 proton/bunch

Edgeless, active to ~ 200 μm from pipe

Radiation hard

Lifetime $> \sim 1$ year at LHC at $L = 10^{34}$

Rate: 25 ns sensitivity

Note: time difference only used,
calibrated with common DPE events.

Time sum would provide additional rejection
iff central event time well known ...
needs added timing capability to central detectors
(Forward region also (HF) : as veto by timing)

SiPM (MCP-PMT option)

L-BAR QUARTIC: LBQ

Principle: All Cherenkov light is totally internally reflected to back of radiator bar. $\sim 2/3$ goes up light guide bar promptly, rest follows.

Total Internal Reflection:
Bars separated by fine wire (100 μm)

Design of test module (made 2)

Will inject light pulses at front of each bar for monitoring

Test beam L-bar QUARTIC box (1 of 2)

Steve Hentschel (Fermilab)

Four units in test beam, 2mm x 2mm trigger counter + 40mm MCP-PMT reference

trigger counter

(Drawings glued on boxes for alignment only)
Two boxes can be slid apart in z

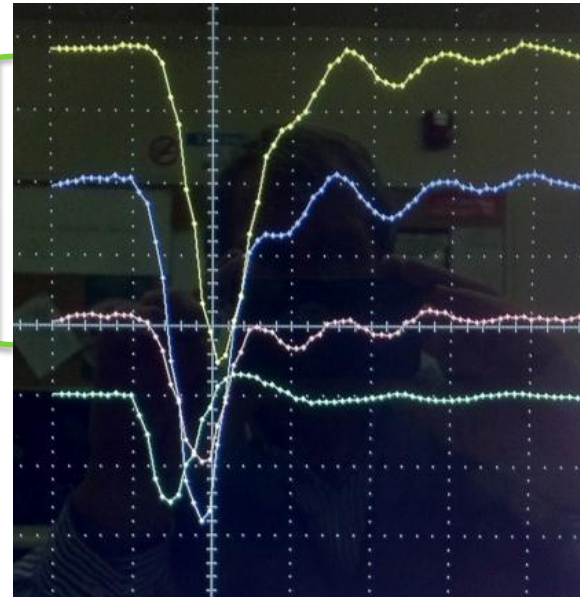

→ DRS4 5 GHz waveform digitiser
200 ps/point 20 mV/div. & 2 ns/div)

$$\sigma(t) = 30 \text{ ps/bar} = 15 \text{ ps/4bars}$$

Technical issues solved, but radiation levels in SiPM "cave" still under evaluation

One event:
3 bars in line

MCP-PMT ref

Several improvements possible → 10 ps
Option: Improved MCP-PMT replacing SiPMs

L-BAR QUARTICs

Front View

Back View

One L-bar QUARTIC module
15mm x 12mm, 20 3x3mm² elements

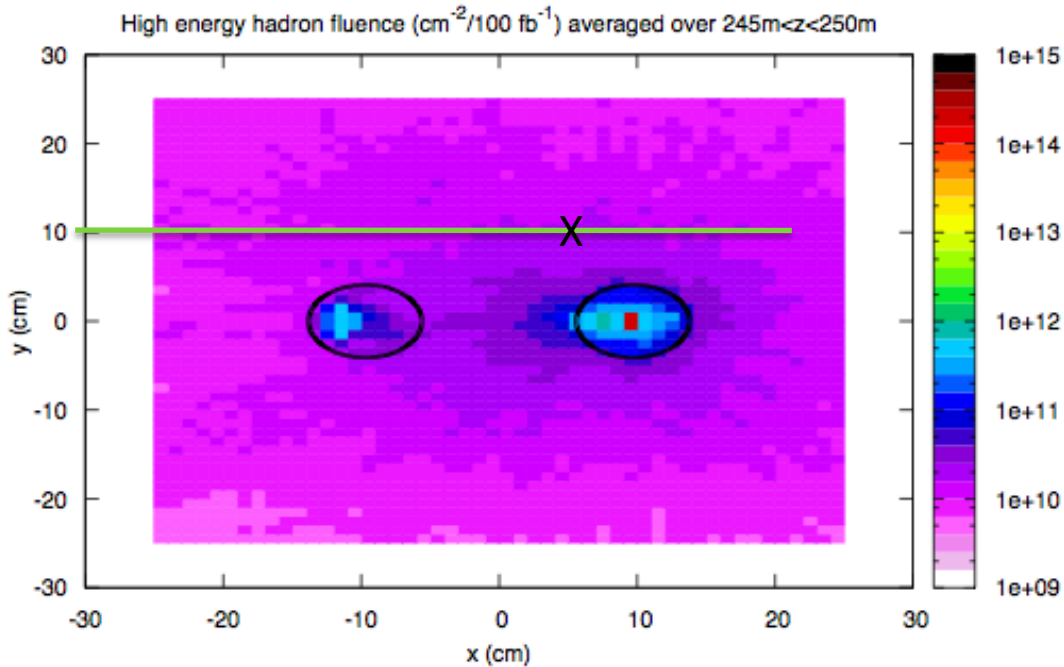

Set of four modules on support...
and in moving pipe assembly:

Having SiPMs out of beam plane
minimizes radiation exposure

Light guide bars to be > 4 cm
but as short as radiation levels allow
Shorter \rightarrow better timing

Mounting for SiPM array board

Hadron fluences fall fast with y : few $10^{10} / \text{cm}^2$ at $y = 10\text{cm}$ in 100 fb^{-1}
Can also shield at that position

Reference Timing system

How to synchronize two points separated by a significant distance?

LLNL adapting system demonstrated by SLAC for LCLS experiments.

RF cable with feedback to keep clocks synchronized at each end

Measured timing jitter = 1.2 ps/C using LCLS spare system and 520 m coax

=> well within HPS timing requirements

Jitter < 2 ps at stations
500 m apart.
input to TDCs

27

Summary of Situation (February 2013)

HPS @ 240 - 250 metres: Installation during LS1 in 2014 or 2015-16 shutdown, pipe sections with tracking and timing detectors.

This is Stage 1 . Making proposal to CMS, hope for approval/funding “soon”

Some colleagues are working with TOTEM on a fully Roman pot solution (back moving pipe replaced with a triplet (probably) of Roman pots)

... INFN Italy + Brazil groups. (next talk?)

We will see what develops.

HPS@240 is a learning step towards HPS @ 420: Installation in ~2016-18; new connecting cryostats and four (2x2) stations with tracking and timing detectors. 240+420 and 420+240 are important combinations

Join the exclusive crowd of forward-looking people!

Thank you

(not confirmed):

This is NOT to do with HPS, but interesting anyway!
 Exclusive central $\pi^+ \pi^-$ production

CDF(Tevatron)
 Gap + $[\pi^+\pi^-]$ + Gap
 $\Delta y(\text{Gaps}) > 4.6$

$L_{\text{eff}}(\text{no-PU}) = 1.18/\text{pb}$ at 1960 GeV

$\sigma(M > 1 \text{ GeV}) \sim 2 \mu\text{b}$
 100/s with 1300b at $\mu = 0.3$
 If efficient trigger, about
 1 hour of LHC data!
