

Exclusive production of WW with AFP

Oldřich Kepka

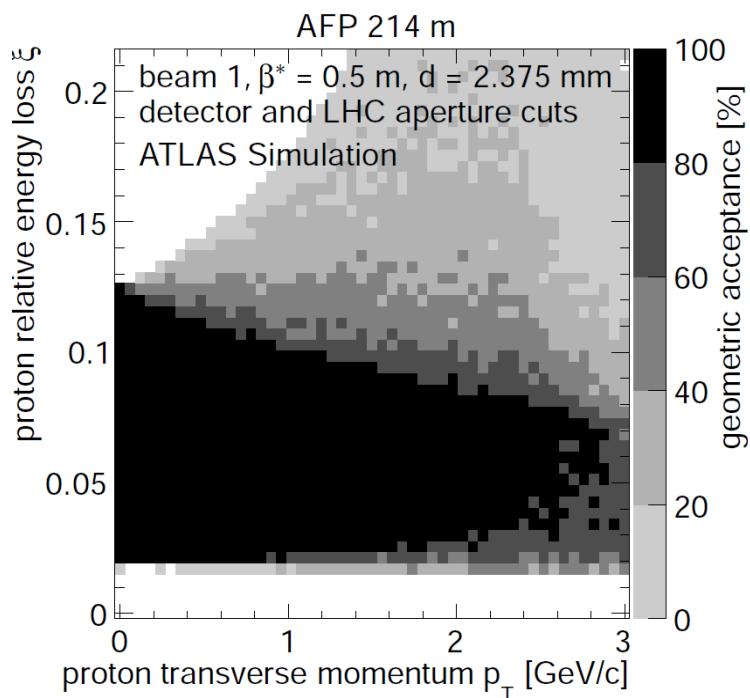

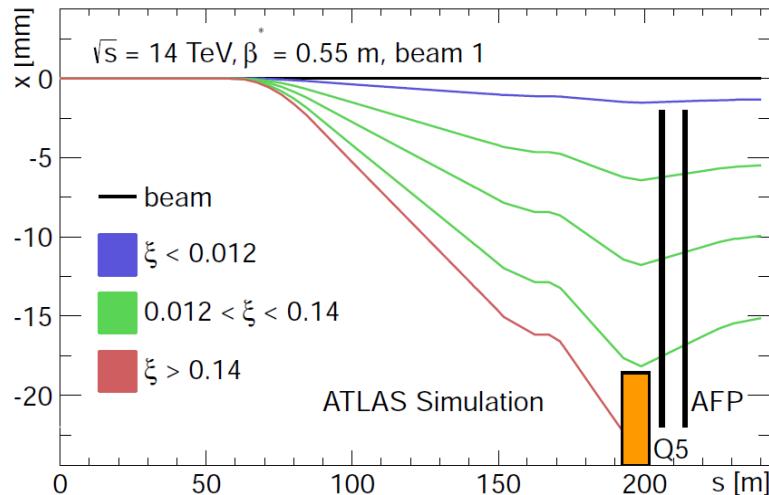

Institute of Physics, Academy of Sciences, Prague
On Behalf of AFP Working Group

February 12th, 2013, CERN

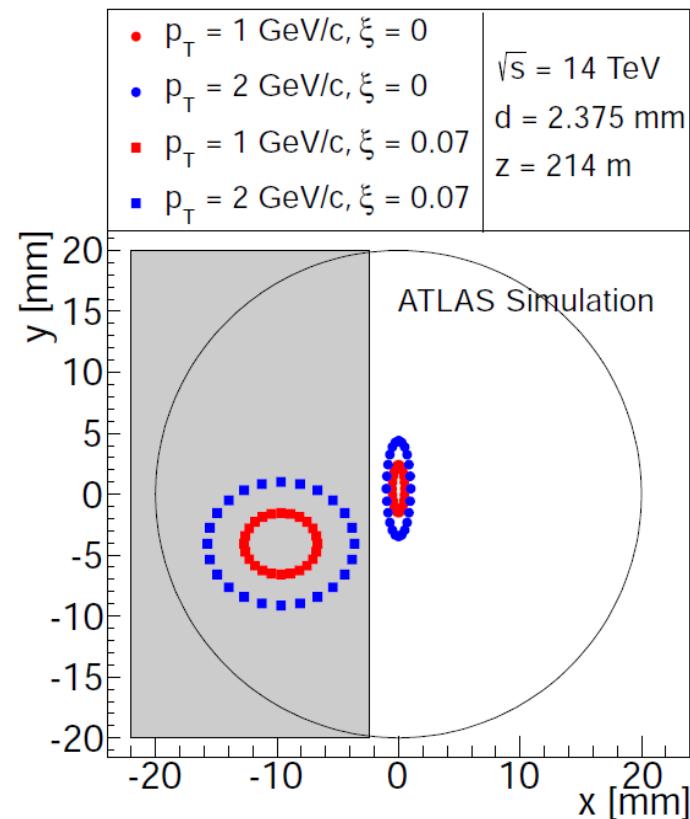

Outline

- Summary of proton detection capabilities at 210 m from IP
- Sensitivity to anomalous quartic gauge boson couplings
 - Analysis with no pile-up 210 + 420m
 - Analysis using full simulation of ATLAS with pile-up for 210 case
- Pile-up forward proton rates using MC
- Summary

Forward protons

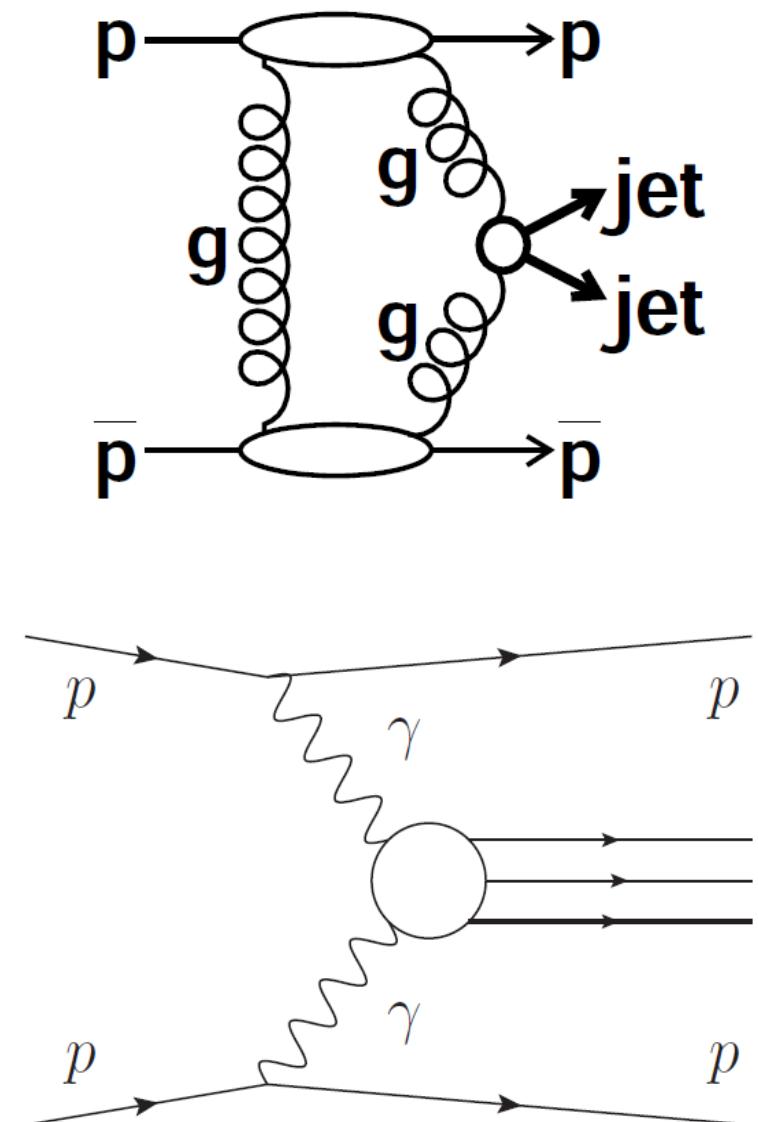

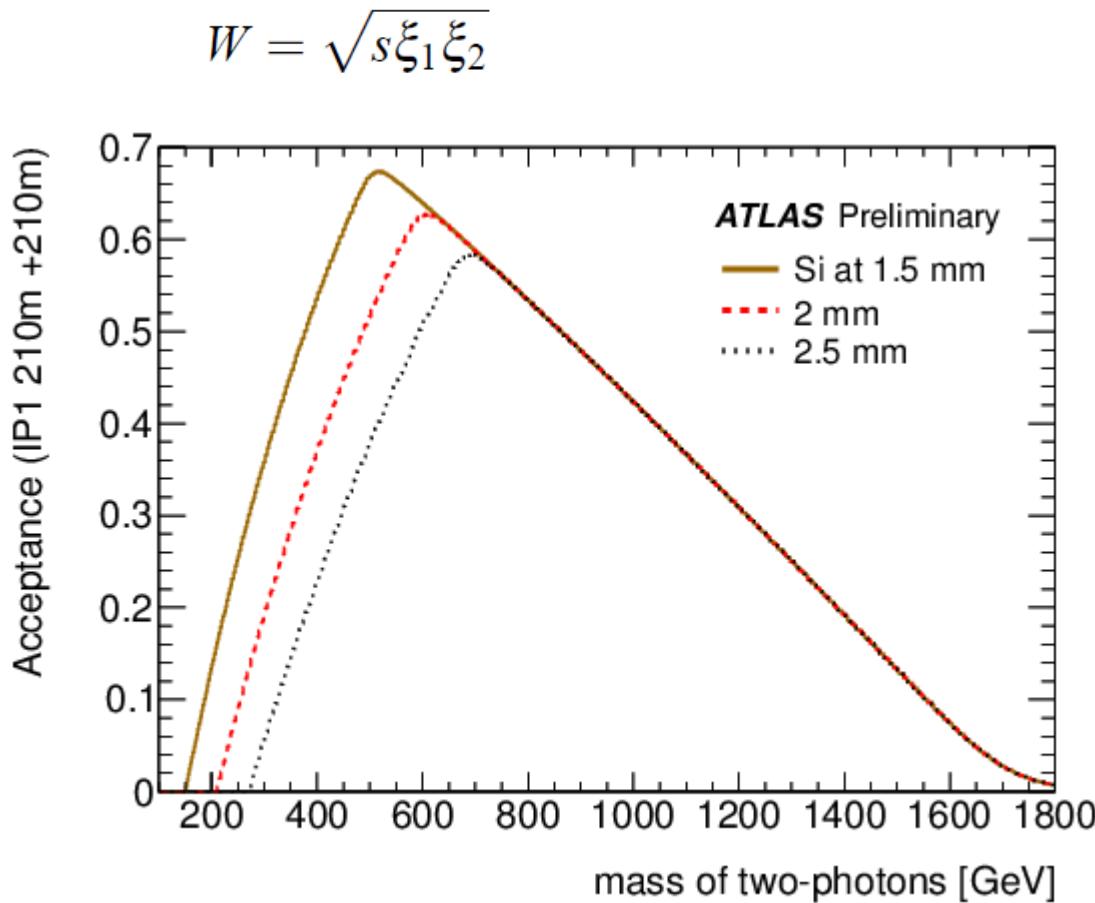

- For increasing relative proton momentum loss $\xi \approx (1-E/E_0)$ protons scatter outside the ring
- Acceptance large for $0.012 < \xi < 0.14$
- d at 15σ : $2.3\text{mm} = 0.13 \times 15 + 0.3$ mm

Acceptance

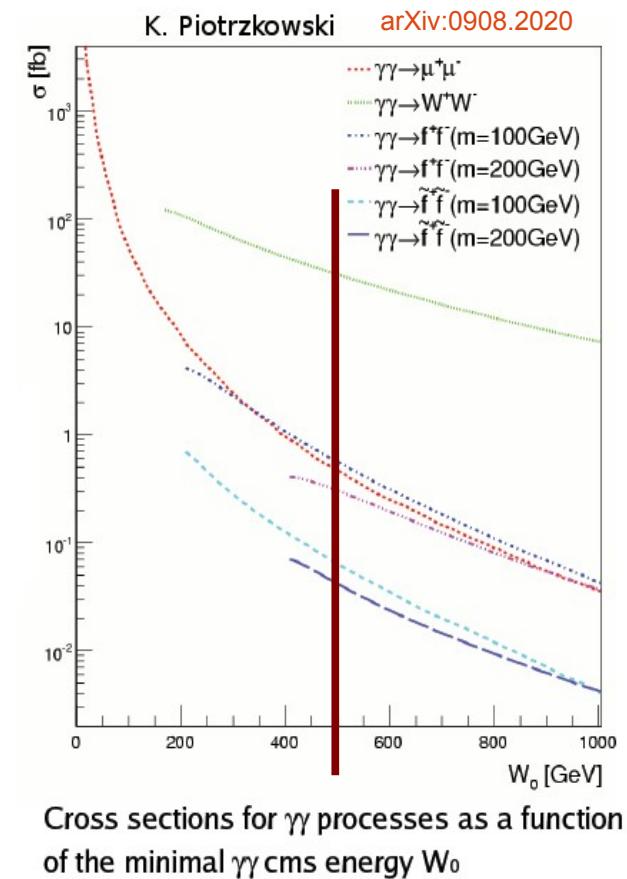

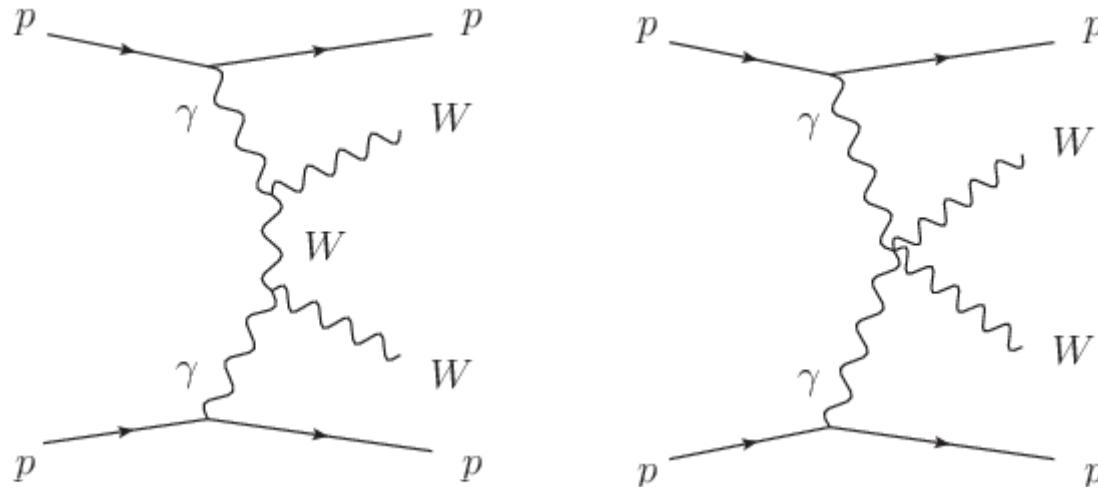

- Acceptance up to $\sim 1\text{TeV}$ scale
- Very small acceptance below 350 GeV

Exclusive QED production

VBS in exclusive mode

- AFP turn LHC pp machine into an effective photon-photon collider
 - But also gamma-pomeron
- Photon induced vector boson scattering process
 - No particle produced from underlying event involving MPI
 - No color flow – possible jet gaps as in VBF

- Improving anomalous TGC/QGC constraints showed on hadron level
 - Exciting mainly for anomalous aQGC, sensitivity to aTGC comparable with existing limits

Anomalous Quartic Gauge Coupling

- Stringent test of the electroweak symmetry breaking by proton tagging
SM: $\gamma\gamma WW$ **BSM:** $\gamma\gamma ZZ, (\gamma\gamma\gamma\gamma)$
- aQGC $\gamma\gamma \rightarrow WW$ can be measured very precisely looking in deviations in $m(\gamma\gamma)$, or $p_T(\text{lep})$ spectrum $\rightarrow \sim 10^{-6}$
- 4 orders of magnitude improvement wrt. LEP
 - Hadron level analysis considering diffractive background with primary int.

Couplings	OPAL limits [GeV $^{-2}$]	Sensitivity @ $\mathcal{L} = 30$ (200) fb $^{-1}$ 5σ	95% CL
a_0^W/Λ^2	$[-0.020, 0.020]$	$5.4 \cdot 10^{-6}$ $(2.7 \cdot 10^{-6})$	$2.6 \cdot 10^{-6}$ $(1.4 \cdot 10^{-6})$
a_C^W/Λ^2	$[-0.052, 0.037]$	$2.0 \cdot 10^{-5}$ $(9.6 \cdot 10^{-6})$	$9.4 \cdot 10^{-6}$ $(5.2 \cdot 10^{-6})$
a_0^Z/Λ^2	$[-0.007, 0.023]$	$1.4 \cdot 10^{-5}$ $(5.5 \cdot 10^{-6})$	$6.4 \cdot 10^{-6}$ $(2.5 \cdot 10^{-6})$
a_C^Z/Λ^2	$[-0.029, 0.029]$	$5.2 \cdot 10^{-5}$ $(2.0 \cdot 10^{-5})$	$2.4 \cdot 10^{-5}$ $(9.2 \cdot 10^{-6})$

T. Pierzchala et al, Nucl. Phys. Proc. Suppl. 179-180 (2008) 257

- Effective Lagrangian:
 - Conserve C, P, T , and custodial symmetries

$$\begin{aligned} \mathcal{L}_{\text{eff}}^{\text{BSM}} = & - \frac{e^2}{8} \frac{a_0^W}{\Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+\alpha} W^{-}_\alpha - \frac{e^2}{16} \frac{a_C^W}{\Lambda^2} F_{\mu\alpha} F^{\mu\beta} (W^{+\alpha} W^{-}_\beta + W^{-\alpha} W^{+}_\beta) \\ & - \frac{e^2}{16 \cos^2 \theta_W} \frac{a_0^Z}{\Lambda^2} F_{\mu\nu} F^{\mu\nu} Z^\alpha Z_\alpha - \frac{e^2}{16 \cos^2 \theta_W} \frac{a_C^Z}{\Lambda^2} F_{\mu\alpha} F^{\mu\beta} Z^\alpha Z_\beta \end{aligned}$$

Details of the analysis

- Use both 210m and 420m detectors
- Consider: $\gamma\gamma$ and double pomeron exchanges
- Neglect pile-up
- Not a realistic scenario anymore
- Large rates of SM process at low mass

- Since anomalous shows up at high mass, 420m actually not needed ...

Implementation of the aQGC

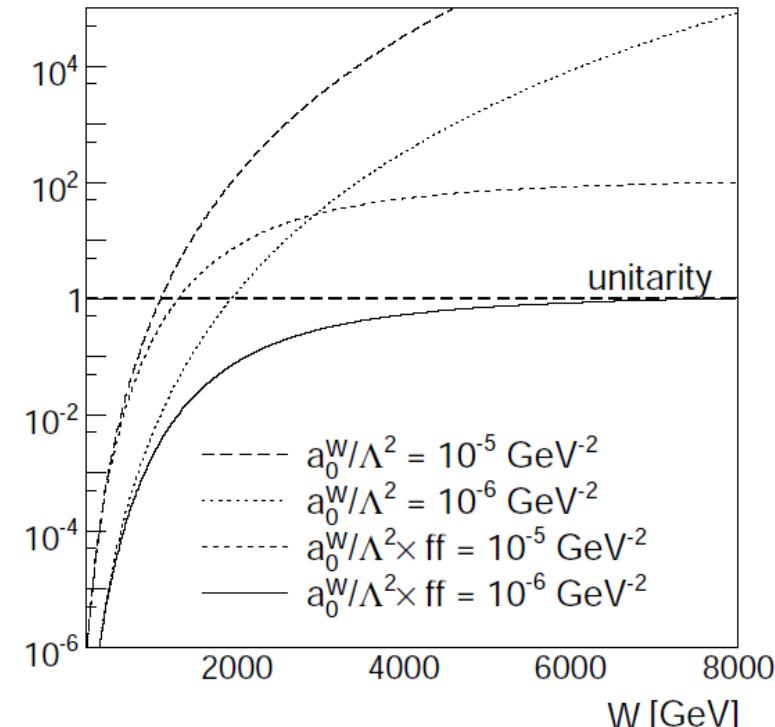

New couplings violate unitarity, couplings need to be accompanied by Form factors regularizing the effect of cross section at high mass

$$a \rightarrow \frac{a}{[1 + (W_{\gamma\gamma}/2 \text{ TeV})^2]^2}$$

- Unitarity condition for anomalous coupling (J. P. Eboli) as a function of the invariant mass measured in AFP

$$\frac{1}{N} \left(\frac{\alpha a s}{16} \right)^2 \left(1 - \frac{4M_W^2}{s} \right)^{1/2} \left(3 - \frac{s}{M_W^2} + \frac{s^2}{4M_W^4} \right) \leq 1 \text{ for } V = W$$
$$\frac{1}{N} \left(\frac{\alpha a s}{16 \cos^2 \theta_W} \right)^2 \left(1 - \frac{4M_Z^2}{s} \right)^{1/2} \left(3 - \frac{s}{M_Z^2} + \frac{s^2}{4M_Z^4} \right) \leq 1 \text{ for } V = Z$$

- It shows that for coupling of the order $\sim 10^{-6}$ unitarity is not violated
- Moreover: Acceptance of AFP serves as a natural cutoff
- Limits do NOT differ by more than factor of 2 with or without ff.

Improvements of the analysis

- Consider multiple proton – proton collisions
- Aim at higher luminosities, and up to 46 interactions per bunch crossings
- Try to avoid missing energy
- Is this possible? Yes, the crucial points are:
 - Timing detectors
 - Counting tracks in the inner detector

Suppression of pile-up

- Require difference between proton arrival times compatible with primary vertex

$$z_0 = \frac{c}{2} (t_1 - t_2) \quad \Delta t_{1,2} = 10 \text{ ps} \rightarrow \Delta z_0 = 2.1 \text{ mm}$$

- Smearing both in time and position -
rejection at 1σ level (2.1mm)

Summary:

- Acceptance

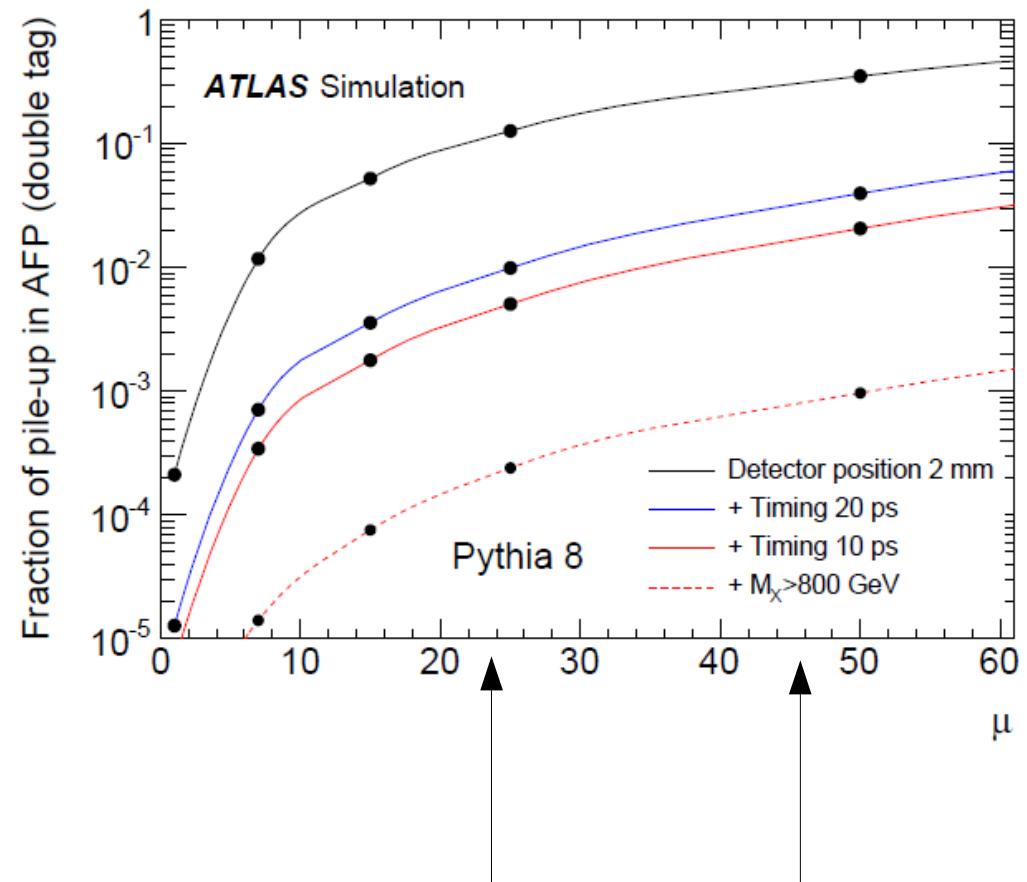

$$\mu = 23: 10^{-1} \quad \mu = 46: 3 \times 10^{-1}$$

- +10ps timing

$$\mu = 23: 4 \times 10^{-3} \quad \mu = 46: 2 \times 10^{-2}$$

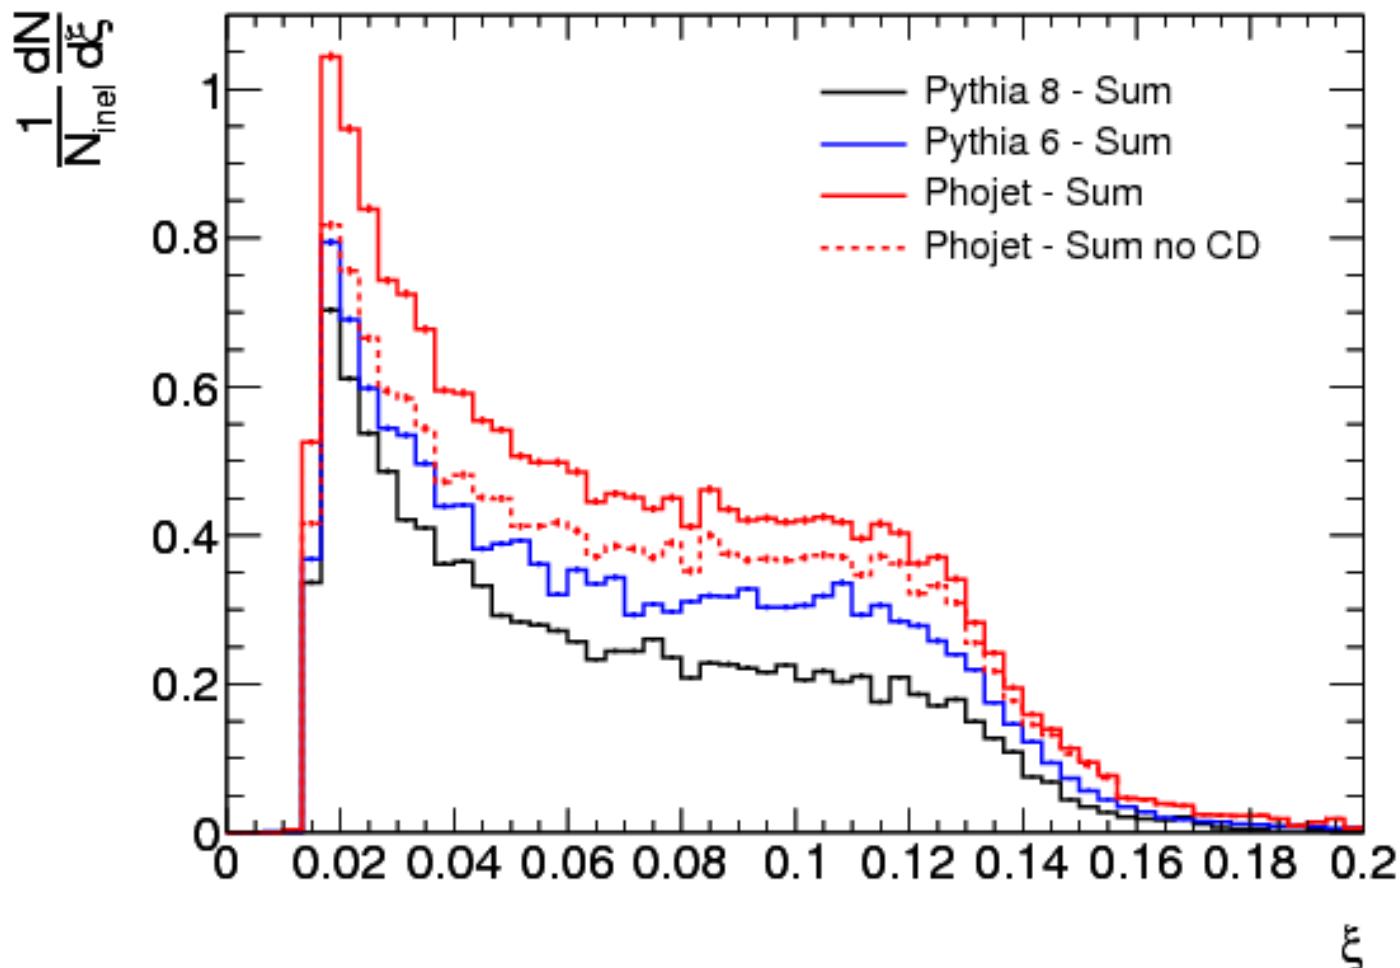

- +High mass $W > 800 \text{ GeV}$

$$\mu = 23: 2 \times 10^{-4} \quad \mu = 46: 10^{-3}$$

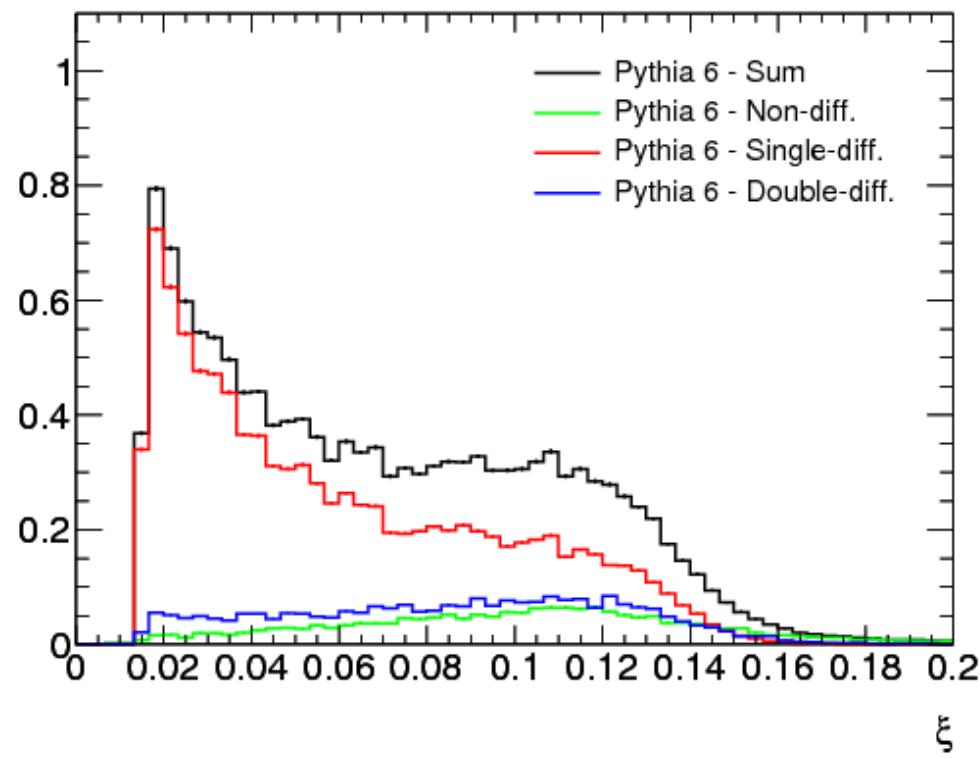

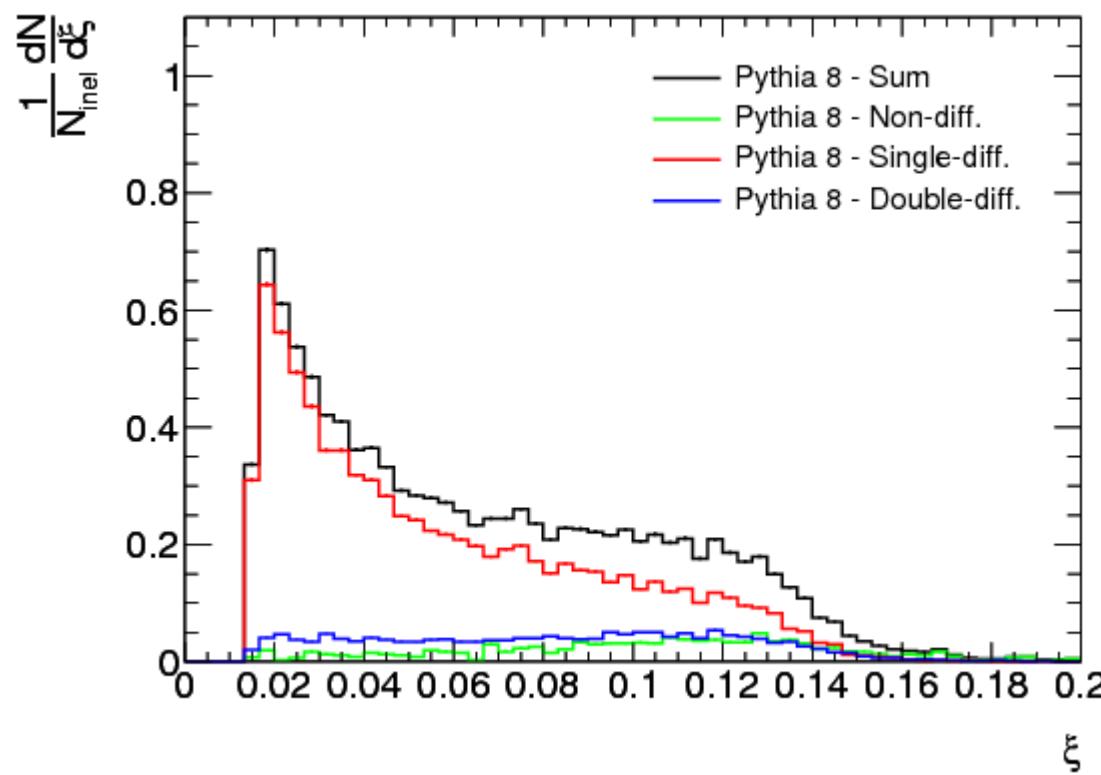

Modeling of pile-up

- Differences between models yield uncertainty in the modeling of pile-up rates in AFP
- Largest deviation for Phojet by factor of 2,
- Constraining the pile-up rates with existing models – Phojet has problems describing ATLAS rapidity gap measurement around $\xi \sim 0.1$.

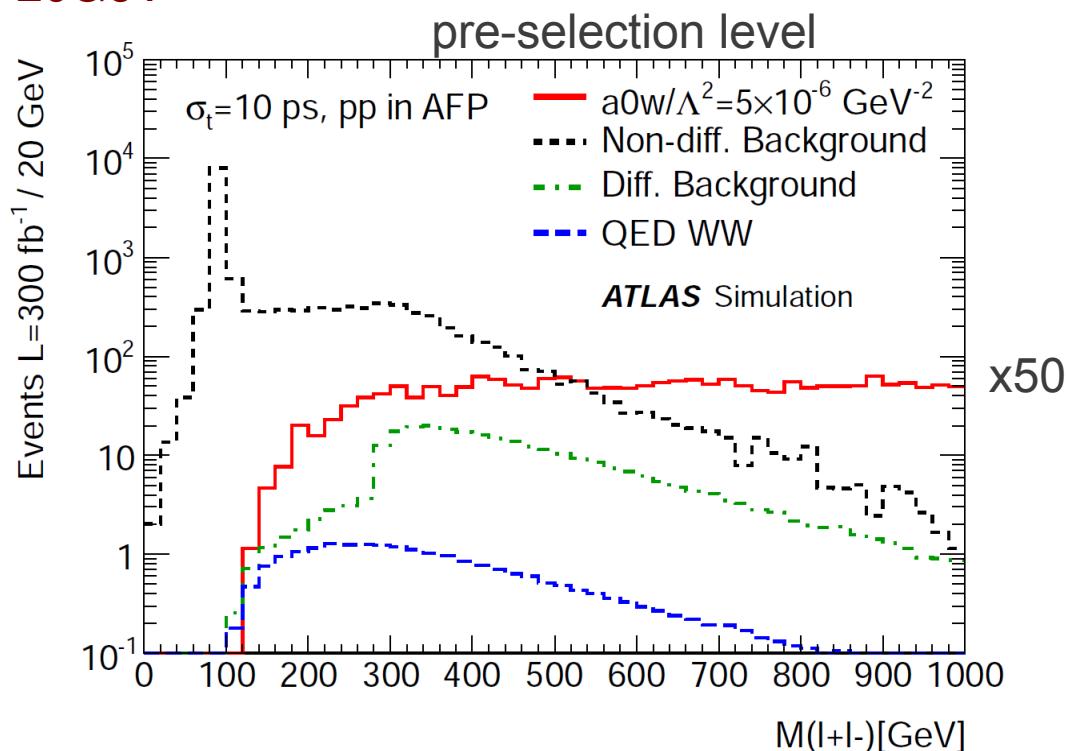

Pythia 6 / 8

- Differences in the modelling of large xi region – uncertainty ~ 30%
- Significant contribution of the non-diffractive and double diffractive events
- Forward physics community should aim at constraining the prediction (ALFA/TOTEM)

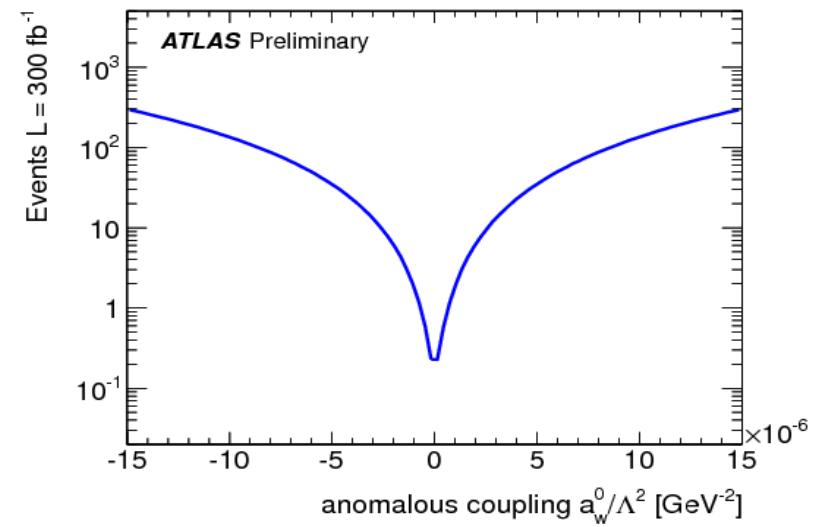

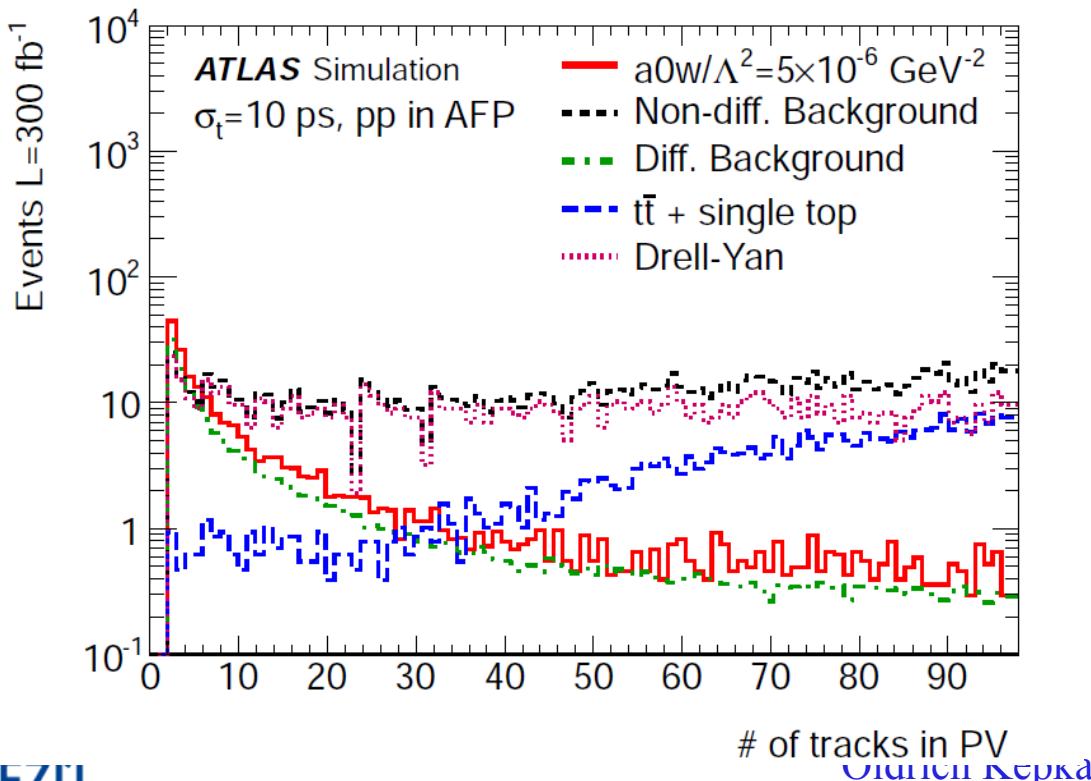

Event selection

- Protons tracked through magnetic field of LHC, detector position at 206, 214m @ 1.5 mm from the beam (FPTracker), AFP approximate acceptance $0.02 < \xi < 0.14$
- Analysis for medium pile-up $\mu=23$
 - $p_T(\text{lead lep}) > 150 \text{ GeV}$ $p_T(\text{sub-lead lep}) > 20 \text{ GeV}$
 - $m(l\bar{l}) > 300 \text{ GeV}$
 - $N_{\text{tracks}} \leq 3$
 - $\Delta\phi(l\bar{l}) < 3.1 \text{ rad}$
 - $m_x > 800 \text{ GeV}$
- Analysis for high pile-up $\mu=46$
 - increase lepton threshold
 - $p_T(\text{lead lep}) > 300 \text{ GeV}$
- Considering complete background set as in ATLAS/CMS WW analyses with central detector

Event selection

- Exclusivity cut – number of tracks ≥ 3 ($p_T > 500\text{MeV}$)
 - Main improvement wrt. hadron level studies, which couldn't use tracks without a realistic simulation of tracker and pile-up
- Non-diffractive productions has larger tails
 - Tracker and vertexing performs extremely well in pile-up
- Fully simulated samples for 4 couplings, dependence fitted with a formula including polynomial and exponential distribution

Final limits

- Fully simulated samples for 4 couplings, dependence fitted with a formula including polynomial and exponential distribution
- Background of the order of ~0.5 events in both $\mu=23$ and 46 scenarios

Cuts	Top	Dibosons	Drell-Yan	W/Z+jet	Diffr.	$a_0^W / \Lambda^2 = 5 \cdot 10^{-6} \text{ GeV}^{-2}$
timing < 10 ps $p_T^{lep1} > 150 \text{ GeV}$ $p_T^{lep2} > 20 \text{ GeV}$	5198	601	20093	1820	190	282
$M(l\bar{l}) > 300 \text{ GeV}$	1650	176	2512	7.7	176	248
nTracks ≤ 3	2.8	2.1	78	0	51	71
$\Delta\phi < 3.1$	2.5	1.7	29	0	2.5	56
$m_X > 800 \text{ GeV}$	0.6	0.4	7.3	0	1.1	50
$p_T^{lep1} > 300 \text{ GeV}$	0	0.2	0	0	0.2	35

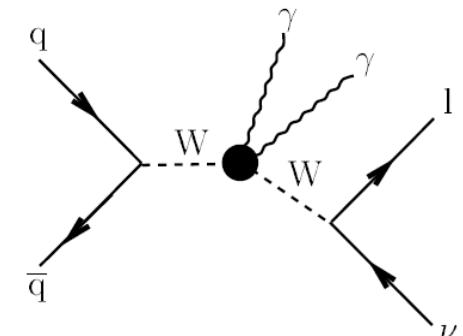

- Final obtained limits

	a_0^W / Λ^2 Sensitivity	
	5σ	95% C.L.
$\mathcal{L} = 40 \text{ fb}^{-1}, \mu = 23$	$5.5 \cdot 10^{-6}$	$2.4 \cdot 10^{-6}$
$\mathcal{L} = 300 \text{ fb}^{-1}, \mu = 46$	$3.2 \cdot 10^{-6}$	$1.3 \cdot 10^{-6}$

- Precision of $\sim 10^{-6} \text{ GeV}^{-2}$ where the BSM effect could show-up maintained
- Mainly due to exclusivity requirement

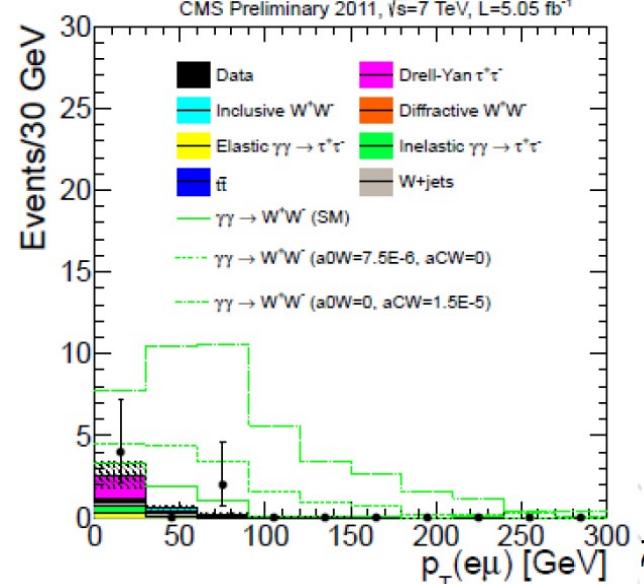

Comparison with existing methods

- $W\gamma\gamma$ – binned maximum likelihood fit of $M\gamma\gamma$ distribution
 - Unitary safe limits improve lep results by two orders of magnitude
 - Background from mis-identified $W+jets$ events
 - AFP adds 1-2 orders better sensitivity

P. J. Bell, Eur.Phys.J.C64:25, 2009

- New CMS preliminary result
 - Exclusive production without tagging, results very promising, exact sensitivity to be determined ..
 - Same models should be compared between **AFP and conventional method** (are these unitary safe limits?)

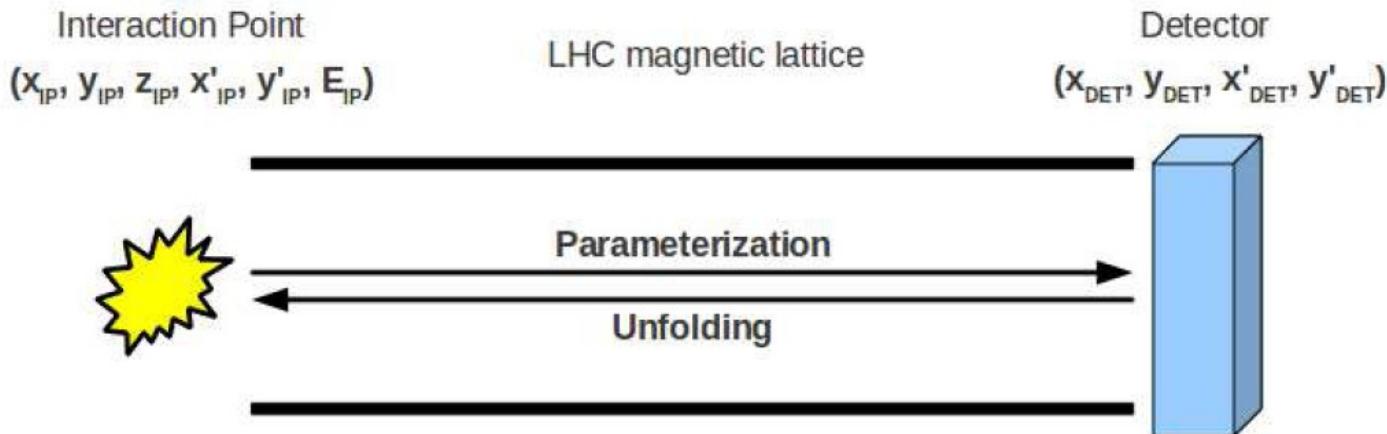

CMS PAS FSQ-12-010

Summary

- Feasibility study of search for high mass object decaying into leptons in exclusive events using detector stations at 210m from IP
 - Key points – tracking, timing of protons (do not need very high timing resolution)
- By 1-2 orders of magnitude better sensitivity than the conventional method
 - Analysis of W expects sensitivity $\sim 10^{-4}$ only, competition sensitivity on exclusive WW with 8TeV data to be seen
- Anomalous $\gamma\gamma ZZ$ not mentioned, but experimentally simpler than WW – employ correlation of M_x in forward detectors and 4 leptons
- With 420m one could measure DPE/ $\gamma\gamma$ backgrounds directly
 - However, for sensitivity to aQGC not crucial
- More studies to be done:
 - Exclusive production of di-photons as a probe of anomalous coupling
 - Investigation of semi-leptonic decays of WW to improve limits

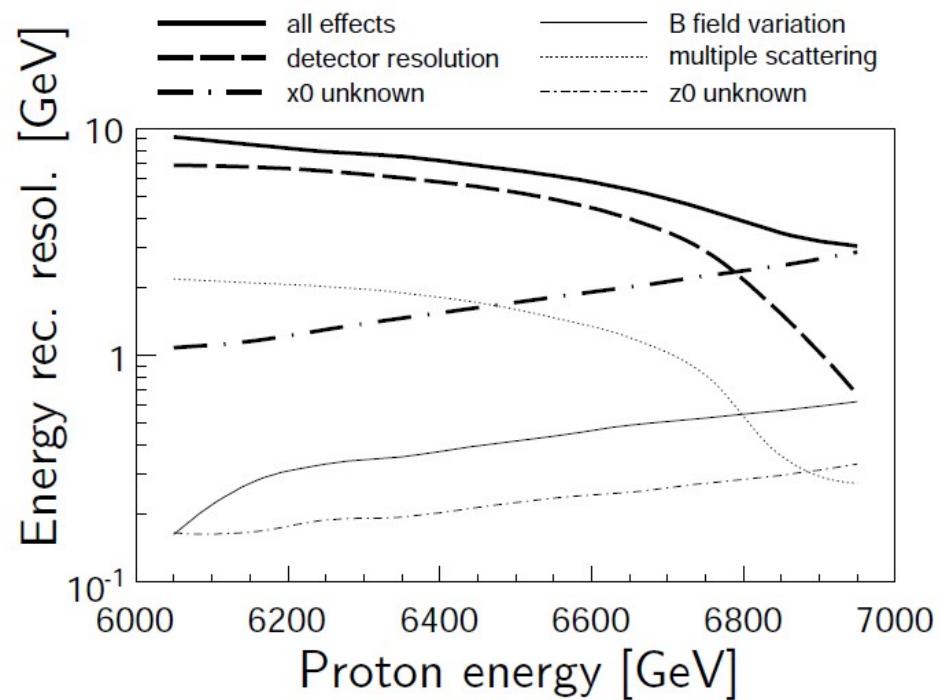

Backup

Proton kinematic reconstruction

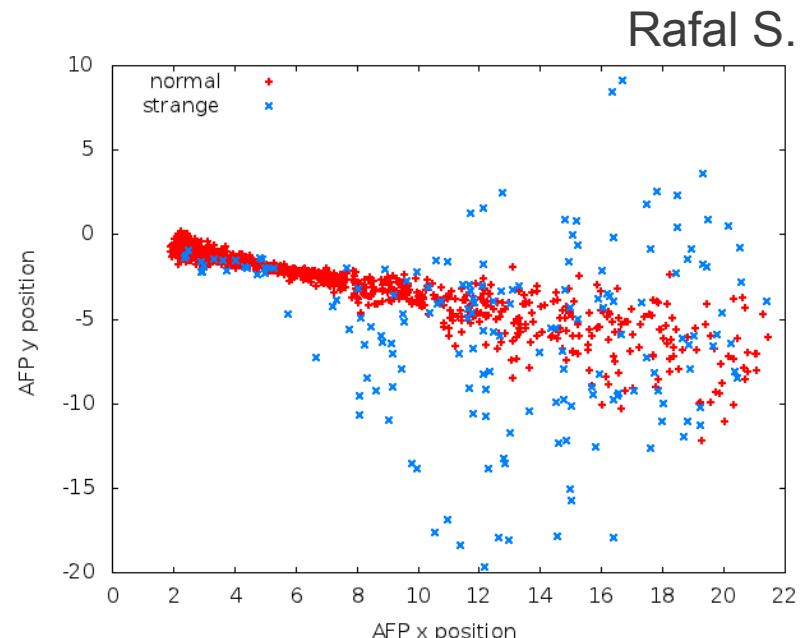

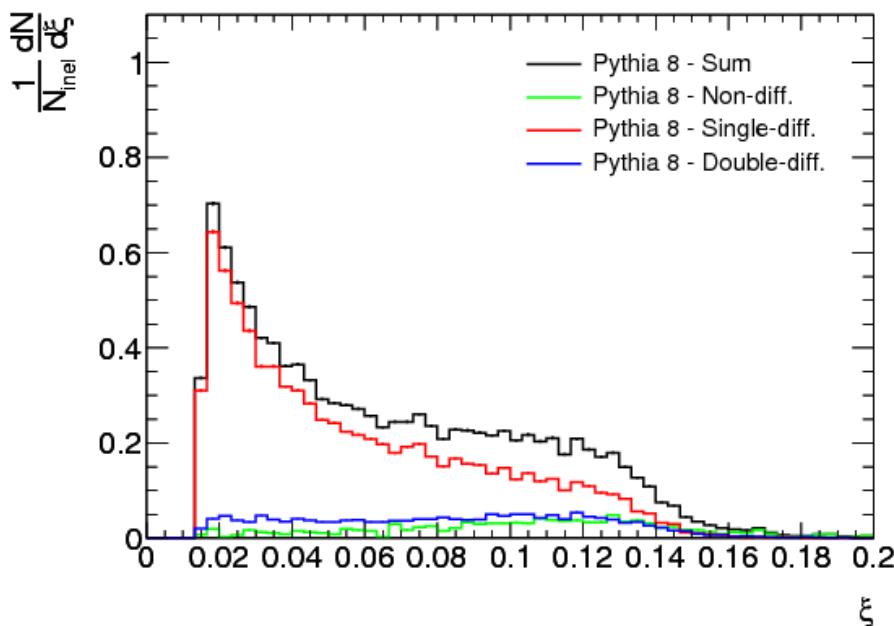

Knowing proton position at both AFP stations one can reconstruct energy and momentum at the Interaction Point.

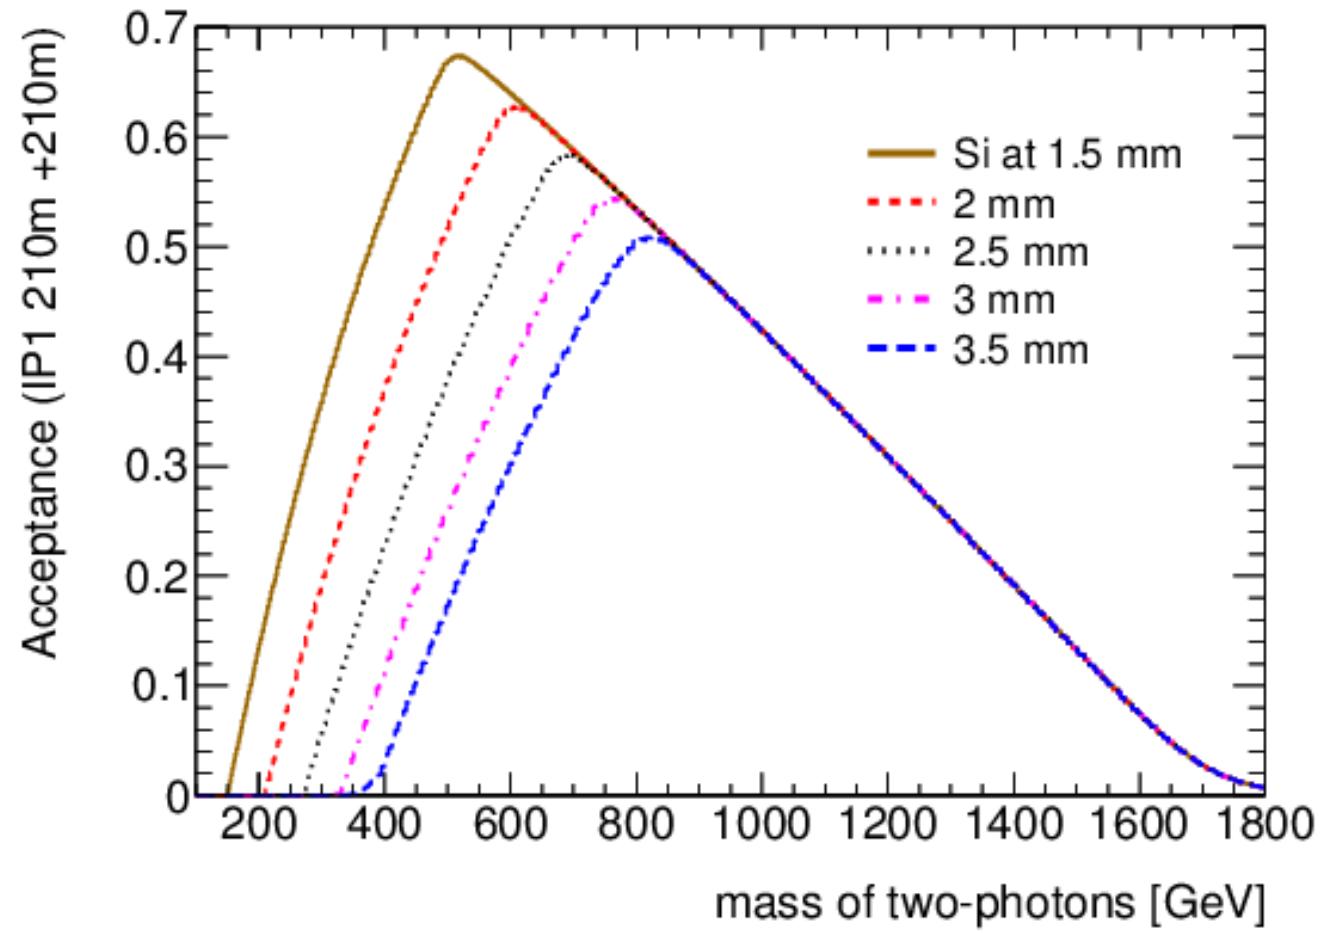

The energy reconstruction resolution is **better than 10 GeV!**

Momentum fraction loss profiles

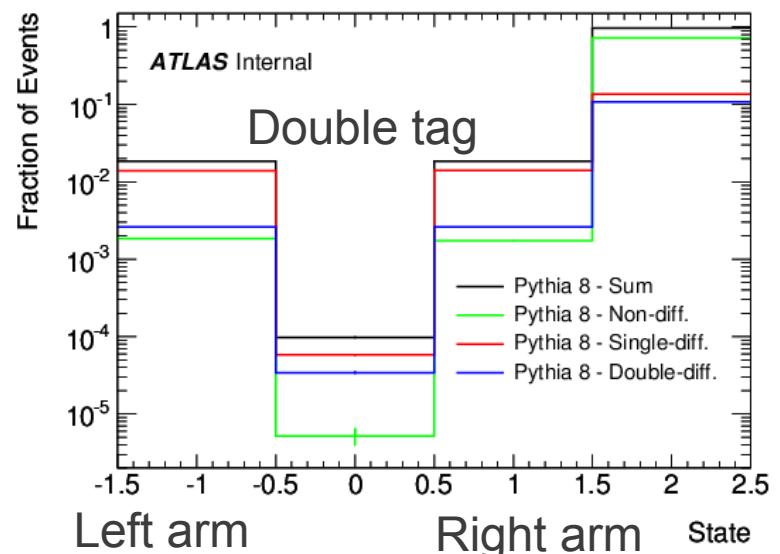

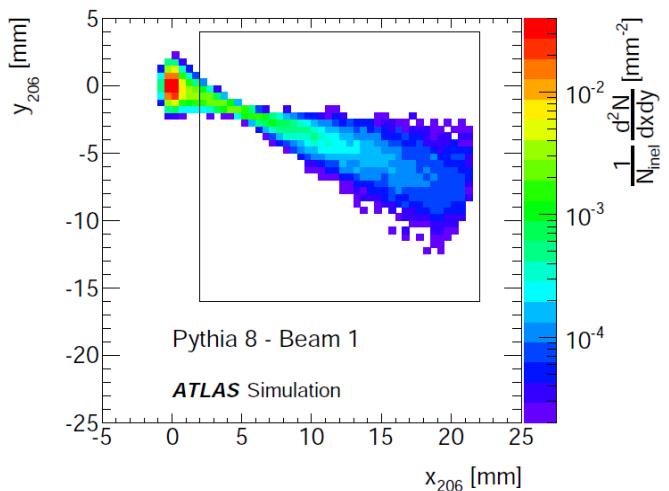

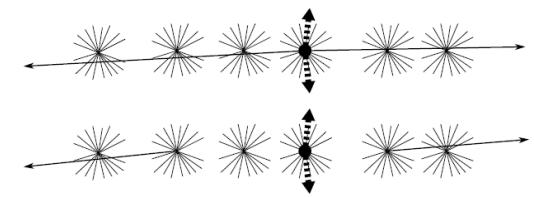

- Intact protons in non-diffractive and double-diffractive sample make about 50% of intact protons hitting AFP
- Right: single diffractive events
 - Comparing side with forward proton and the side with dissociated system
 - Rejection power could be increased by cutting on particular XxY patterens
- Needs to be measured!
 - Starting ALFA diffractive program can provide important constraints to pile-up in AFP

Multiple p-p collisions (Pile-up)

- Non-diffractive event in coincidence with two SD protons from MB events fake signal
- MB interaction hits one detector in 2% cases
- Fake double tag in 0.01% cases
- ND/DD events (and SD on the side of broken proton) also show intact protons especially at high ξ
- Pythia 6 predicts by about factor 10 higher rates than Pythia8
- Starting ALFA diffractive program can provide important constraints to pile-up in AFP

Study with Full Simulation

Signal:

- QED WW SM, with QGC, semi-leptonic decays

Backgrounds

- non-diffractive (+pile-up)
 - WW, WZ, ZZ, Drell-Yan, W/Z+jet, ttbar, single top
- diffractive
 - QED II, SD WW, DPE WW, DPE II
- Neglecting: Photon+Pomeron exchanges
- Generators: FPMC, Herwig++, Pythia8
- Fully simulated samples in Athena rel. 16
 - $\mu=23, 46$ – corresponding to 40 and 300 fb^{-1}
