

Performance of the Latest MPPCs with Reduced Dark Counts and Improved Photon Detection Efficiency

Thursday 5 September 2013 11:40 (20 minutes)

We have tested the performance of two types of the latest Multi-Pixel Photon Counters (MPPCs; measuring $3 \times 3 \text{ mm}^2$ in size) developed by Hamamatsu Photonics K.K. The new S12572-050C is a successor to the S10362-33-050C (i.e., conventional $3 \times 3\text{-mm}^2$ pixel MPPC of $50\text{-}\mu\text{m}$ pitch), comprises 3,600 Geiger mode avalanche photodiodes (APDs), and also features high gain ($\sim 1.25 \times 10^6$), a low dark count ($\sim 10^6$ cps), and improved photon detection efficiency (PDE) of $\sim 35\%$. The S12572-015C is a new type of fine-pitch ($15 \mu\text{m}$) MPPC featuring a wide dynamic range and fast timing response. This paper first presents the detailed performance of these latest MPPCs as photon counting devices. It then describes our fabrication of a prototype detector consisting of a MPPC optically coupled with a Ce:GAGG scintillator. We obtained average FWHM energy resolutions of 9.0% (S12572-015C) and 10.9% (S12572-050C), as compared to 11.7% (S10362-33-050) for 662-keV gamma rays from the ^{137}Cs source, as measured at 20°C . Moreover, the number of fired pixels for 662-keV gamma rays increased by 14.2% for S12572-050C (as compared to S10362-33-050), thus indicating more than a 10% improvement in PDE around the light emission peak of Ce:GAGG at 480 nm. We also confirmed that the low energy threshold improved from 10 keV to 4 keV, when using the latest MPPC device (S12572-050C). The results thus confirm that these new types of MPPCs are promising for various applications as scintillation detectors.
