- Experimental evidences of non-extensive self-consistency.
- Thermodynamical functions and lattice-QCD.
- Conclusions.

The non-perturbative river

QCD is a well-known theory for strong interaction
and works very well for Particle Physics.

In Nuclear Physics it faces some problems: non-perturbative character.

We need a bridge!

Hagedorn's theory

A hadronic system is considered as an ideal gas of hadrons at a temperature T . The partition function is

$$\ln[1 + Z(V_0, T)] = \frac{V_0 T}{2\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \int_0^{\infty} \rho(m; n) m^2 K_2(\beta n m) dm.$$

The bootstrap idea is:

Fireball is “*the static equilibrium of a system composed by *fireballs*, which on their turn are ... (goto *)”

The partition function can also be written as

$$Z(V_0, T) = \int_0^E \sigma(E') Z_0(E') dE'$$

According to the bootstrap principle, both forms of partition function must be asymptotically identical with

$$\ln[\sigma(E')] = \ln[\rho(m)]$$

Self-consistency

Both constraints can be satisfied with

$$\sigma(E) \rightarrow b E^{\alpha-1} e^{\beta_o E}$$

$$\rho(m) \rightarrow m^{-5/2} e^{\beta_o m}$$

And in this case both expression for the partition function reduce to

$$Z(V_o, T) \sim \left(\frac{1}{\beta - \beta_o} \right)^\alpha$$

with

$$\alpha = \frac{aV_0}{(2\pi\beta_0)^{3/2}}$$

Experimental verification

With

$$\bar{\nu}_k = -\frac{1}{\beta} \frac{\partial \ln Z(T)_{\pm}}{\partial \epsilon_k}$$

and using the thermodynamical relations we get

$$\bar{\nu}_k = e^{-\beta_0 \epsilon_k} \Rightarrow \ln(\bar{\nu}_k) = -\beta_0 \epsilon_k$$

It is more useful to write it in terms of the transversal momentum.

Using

$$\epsilon = \sqrt{p_{\perp}^2 + p_z^2 + m^2}$$

we get, for $p_{\perp} \gg T_0 \gg m$,

$$w(p_{\perp}) \approx C \cdot p_{\perp}^{3/2} \exp\left(-\frac{p_{\perp}}{T_0}\right)$$

Phase transition

The exponentially increasing spectrum proposed by Hagedorn is ~~not necessarily connected with a limiting temperature~~, but it is present in any system which undergoes a ~~second order phase transition~~. We suggest that the "observed" exponential spectrum is connected to the existence of a different phase of the vacuum in which quarks are not confined.

1 Introduction

The abundant formation of resonances of increasing mass and rotational degrees of freedom is one of the most striking features of strong interaction physics, which has attracted intense theoretical attention for half a century or more. Even before the quark infrastructure of hadrons was known, a self-similar composition scheme, the statistical bootstrap model (SBM), led to an exponentially increasing resonance spectrum [1, 2]. Shortly thereafter the dual resonance model (DRM) provided a description of hadron interactions in

The partition function of an ideal gas of constituents of mass $m(T)$ is in the Boltzmann limit for $SU(N)$ gauge theory given by

$$\ln Z(T) = 2 \frac{(N^2 - 1)V}{2\pi^2} \int_0^\infty dp p^2 \exp\left(-\frac{1}{T}\sqrt{p^2 + m^2}\right) \\ = 2 \frac{(N^2 - 1)VTm^2}{2\pi^2} K_2\left(\frac{m}{T}\right), \quad (15)$$

where $K_1(x)$ denotes the Hankel function of imaginary argument. The resulting pressure becomes

$$P(T) = T \left(\frac{\partial \ln Z}{\partial V} \right)_T \\ = 2 \frac{(N^2 - 1)T}{2\pi^2} \int_0^\infty dp p^2 \exp\left(-\frac{1}{T}\sqrt{p^2 + m^2}\right) \\ = 2 \frac{(N^2 - 1)T^2 m^2}{2\pi^2} K_2\left(\frac{m}{T}\right) \quad (16)$$

while the energy density is found to be

THE HAGEDORN TEMPERATURE REVISITED

increase determines the value of the Hagedorn temperature, T_H . Recent papers,^{16–21} have used the latest results from the Particle Data Group¹⁵ to revisit the original analysis of Hagedorn to update the value of T_H . This resulted in a surprising wide spread of possible values, with large variations as to whether one considers mesons or baryons with values ranging from $T_H = 141$ MeV to $T_H = 340$ MeV depending on the parametrization used and on the set of hadrons (mesons or baryons). There thus exists uncertainty as to the value of the Hagedorn temperature. These have two origins:

- sparse information about hadronic resonances certainly above 3 GeV,
- the analytical form of the Hagedorn spectrum, especially the factor multiplying the exponential.

Introducing non-extensivity: Bediaga's generalization

Bediaga:

$$x_{ij} = (1 + (q - 1)\beta\epsilon_{ij})^{-q/(q-1)}$$

Partition function:

$$\log Z = - \sum_{ij} \log(1 - x_{ij}) + \sum_{i'j'} \log(1 + x_{i'j'})$$

and ...

$$w(p_{\perp}) \approx \text{const} \cdot p_{\perp} \int_0^{\infty} dp_L (1 + (q - 1)\beta\sqrt{p_{\perp}^2 + p_L^2 + m_0^2})^{-\frac{q}{q-1}}$$

Transverse momentum distribution (C. Beck):

$$\frac{1}{\sigma} \frac{d\sigma}{dp_{\perp}} = c (2(q-1))^{-1/2} B\left(\frac{1}{2}, \frac{q}{q-1} - \frac{1}{2}\right) u^{3/2} (1 + (q-1)u)^{-\frac{q}{q-1} + \frac{1}{2}}$$

with

$$B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$$

Comparison of Bediaga's formula with experiment

Self-consistency in the non-extensive thermodynamics

$$Z_q(V_o, T) = \int_0^\infty \sigma(E) [1 + (q-1)\beta E]^{-\frac{q}{q-1}} dE$$

and

$$\begin{aligned} \ln[1 + Z_q(V_o, T)] &= \frac{V_o}{2\pi^2} \sum_{n=1}^{\infty} \frac{1}{n} \int_0^\infty dm \int_0^\infty dp p^2 \rho(n; m) \\ &\quad \times [1 + (q-1)\beta \sqrt{p^2 + m^2}]^{-\frac{nq}{q-1}}, \end{aligned}$$

The bootstrap principle

$$\begin{aligned} Z_q(V_o, T) &= \int_0^\infty \sigma(E) [1 + (q-1)\beta E]^{-\frac{q}{q-1}} dE \\ &= \exp \left\{ \frac{V_o}{2\pi^2 \beta^{3/2}} \int_0^\infty dm m^{3/2} \rho(m) [1 + (q-1)\beta m]^{-\frac{1}{q-1}} \right\} - 1 \end{aligned}$$

At the same time we must have

$$\ln[\sigma(E)] = \ln[\rho(m)]$$

Mass spectru and density of states

The self-consistency principle is satisfied if

$$m^{3/2}\rho(m) = \frac{\gamma}{m} [1 + (q_o - 1)\beta_o m]^{\frac{1}{q_o - 1}} = \frac{\gamma}{m} [1 + (q'_o - 1)m]^{\frac{\beta_o}{q'_o - 1}}$$

and

$$\sigma(E) = bE^a [1 + (q'_o - 1)E]^{\frac{\beta_o}{q'_o - 1}}$$

Using properties of $\Gamma(z)$ function it results that for $(q'_o - 1) \rightarrow 0$,

$$Z_q(V_o, T) \rightarrow b\Gamma(a + 1) \left(\frac{1}{\beta - \beta_o} \right)^{a+1}$$

Then both expression for the partition function Z_q converge if

$$a + 1 = \alpha = \frac{\gamma V_o}{2\pi^2 \beta^{3/2}}$$

Limiting temperature: β_o and entropic index: q_o .

A. Deppman, Physica A 391 (2012) 6380–6385.

Consistency with thermodynamical functions

Tsallis \rightarrow Thermodynamical relations \rightarrow Bediaga formula?

J.M. Conroy, H.G. Miller and A.R. Plastino

Phys. Lett A 374 (2010) 4581 \rightarrow **No!**

$$n_i = (1 + [1 + (q - 1)\beta(E - \mu)]^{1/(q-1)})^{-q}$$

But for $E \rightarrow \infty$ it reduces to Bediaga formula!

Also: J Cleymans e D Worku: JPG 39 (2012) 025006.

$$\frac{dN}{dp_T} = gV \frac{dN}{dy} \frac{p_T m_T \cosh y}{4\pi^2} \left[1 + (q - 1) \frac{m_T \cosh y - \mu}{T} \right]^{-q/(q-1)}$$

However STAR, PHENIX, ALICE, CMS still use

$$\frac{dN}{dp_T} = p_T \frac{dN}{dy} \frac{(n-1)(n-2)}{nC[nC + m_o(n-2)]} \left(1 + \frac{m_T - m_o}{nC} \right)^{-n}$$

Correlation between T and q

Wilk e Włodarczyk: Cent. Eur. J. Phys. 10 (2012) 568-575

$$T_{eff} = T_o - (q - 1)c$$

$$T_H = (192 \pm 15) \text{ MeV} \quad c = -(950 \pm 10) \text{ MeV}$$

Thermodynamical functions

$$\frac{1}{V} \ln[Z(V, \beta)] = \frac{\gamma(q-1)}{2\pi^2\beta^{3/2}} \left(\frac{1}{(\beta - \beta_0)M(q-1)} \right)^{\frac{1}{q-1}}$$

$$\times {}_2F_1 \left[\frac{1}{q-1}, \frac{1}{q-1}, \frac{q}{(q-1)(\beta - \beta_0)M} \right]$$

pressure $p = \frac{T}{V} \ln[Z(V, \beta)]$ entropy density: $s = \frac{\partial p}{\partial T}$

energy density: $\varepsilon = \frac{T^2}{V} \frac{\partial}{\partial T} \ln[Z(V, \beta)]$

trace anomaly: $a(T) = \frac{\varepsilon - 3p}{T^2} = T \frac{\partial}{\partial T} \left(\frac{p}{T^4} \right)$

Map between non-extensive and extensive quantities

Mapa entre T e τ :

$$\tau(T_o) = \tau_o$$

$$\tau(0) = 0$$

$$\tau(T_1 + T_2) = \tau(T_1) + \tau(T_2)$$

A função que satisfaz essas condições é:

$$\tau(T) = kT = \frac{\tau_o}{T_o} T$$

From here we get the following relations:

$$\frac{p}{T^4} = k^{-3} \frac{k^{-1} p}{(k^{-1} T)^4} = k^{-3} \frac{\pi}{\tau^4}$$

$$s = \sigma$$

$$\varepsilon = k^{-1} \epsilon$$

$$a = k^{-3} \alpha,$$

Conclusions

Comparison to lattice-QCD

Conclusions

- It is possible to obtain a self-consistent theory for fireballs in the non-extensive thermodynamics.
- Self-consistency leads to a limiting effective temperature, T_o , and a limiting entropic index, q_o .
- Experimental data for p_T -distributions give support for the existence of T_o and q_o .
- The mass-spectrum formula describes very well the known hadronic states (mesons and baryons).
- It is possible to find a connection between extensive and non-extensive thermodynamics functions.
- Thermodynamics functions resulting from the non-extensive self-consistent theory are in agreement with lattice-QCD results.
