

The Institut Laue Langevin

Global leadership in neutron science

The Institut Laue Langevin At the service of the European neutron community

- Created in 1967.

- 3 Associates (France, Germany and the United Kingdom)
- 11 scientific members
- A staff of 500 people
- An annual budget > 80 M€
- An investment share of 20 %

The Institut Laue Langevin:

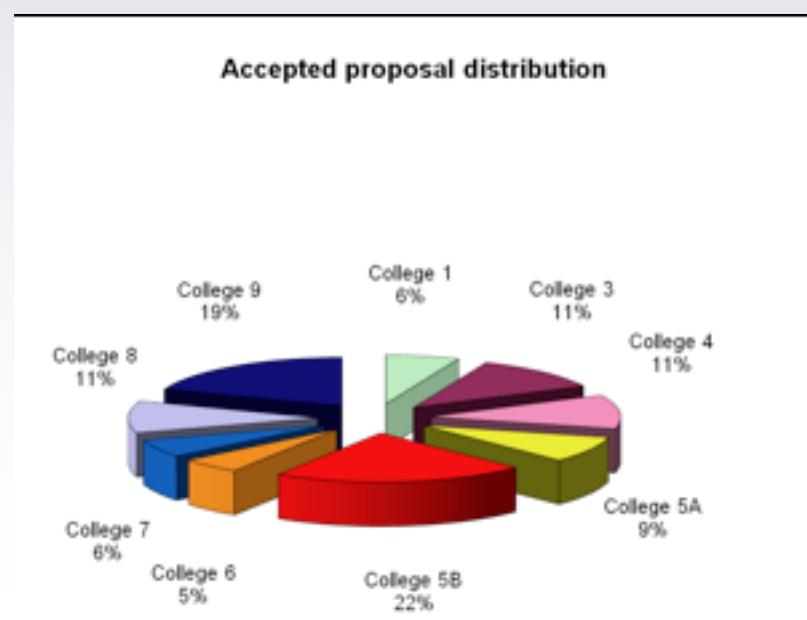

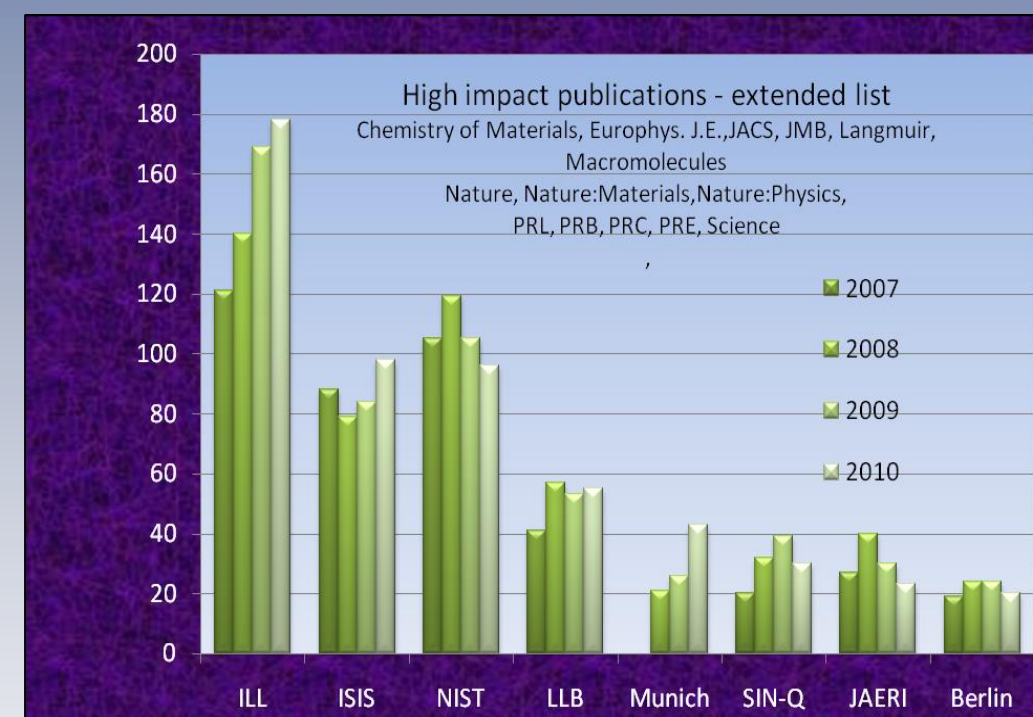

A reference in terms of knowledge creation within the neutron community

1400 peer reviewed proposals

2000 users

800 experiments

600 publications

Continuous upgrading of the scientific infrastructure

- The « Millennium Programme » has allowed to increase the overall performance by a factor of 20.
- ILL-2020 is on ESFRI roadmap.

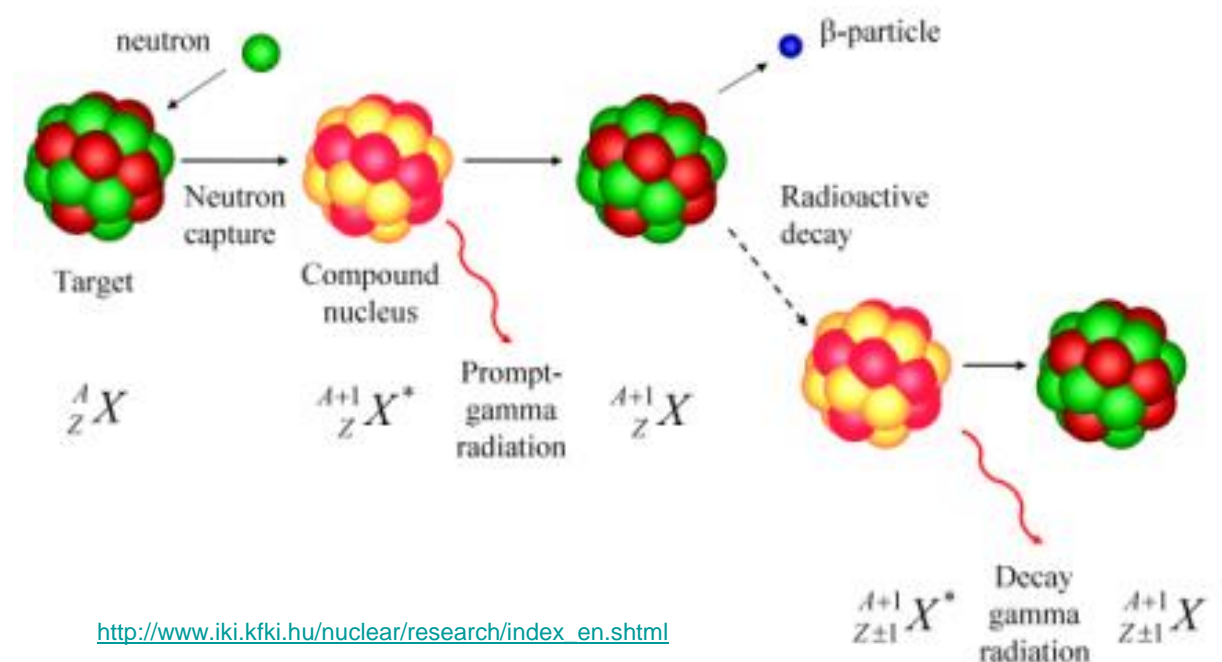

Science enabled by neutron sources

Helmut Schober
Institut Laue Langevin

The neutron as probe of matter

From the elementary particle to macroscopic objects

http://www.iki.kfki.hu/nuclear/research/index_en.shtml

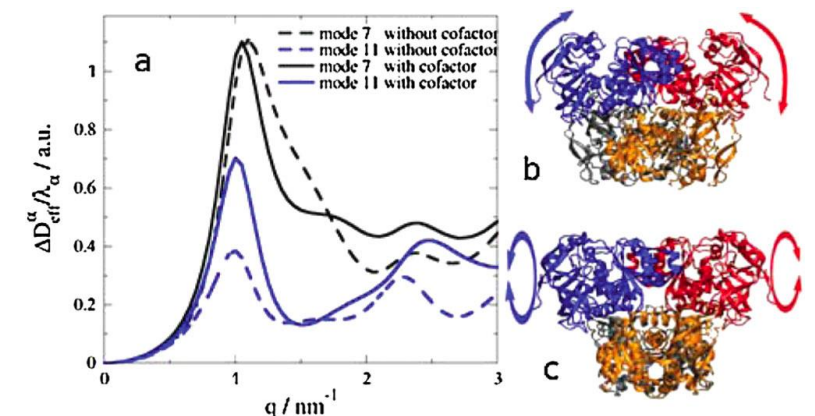

The decisive properties of the neutron

- Electrically neutral.
- Interacts with the nuclei via the strong interaction.
- Carries a magnetic moment.
- Possesses a mass slightly above that of the proton.
- Consequences:
 - Simple theoretical description (Born approximation).
 - Isotope specific contrast.
 - Gentle and deeply penetrating.
 - Extreme sensitivity towards magnetism.
 - Extremely sensitive to microscopic dynamics (fs to μ s).

DNA without H

DNA with H

The specific case of scattering

Neutron wavelength correspond to typical microscopic length scales in matter.

The corresponding neutron energies match very well the typical excitation energies of these objects.

From 1000 nm
and μs (~ 1 neV)

$$\Delta\phi = \frac{\Delta y}{D} = \frac{\lambda}{d}$$

down to 0.001 nm
and 10 fs (~ 500 meV)

How to produce free neutrons

Fission

Spallation

Spaltung

● Proton
● Neutron

Spallation

180 MeV/neutron for a reactor 20 MeV/neutron for a spallation source
A 1 MW spallation source creates at least the same costs as a 60 MW reactor

As produced neutrons have
extremely high energies

In the case of spallation
the mean energies are
even higher.

Fig. 2.6.1. The energy spectrum of neutrons produced in
thermal neutron fission of U^{235}

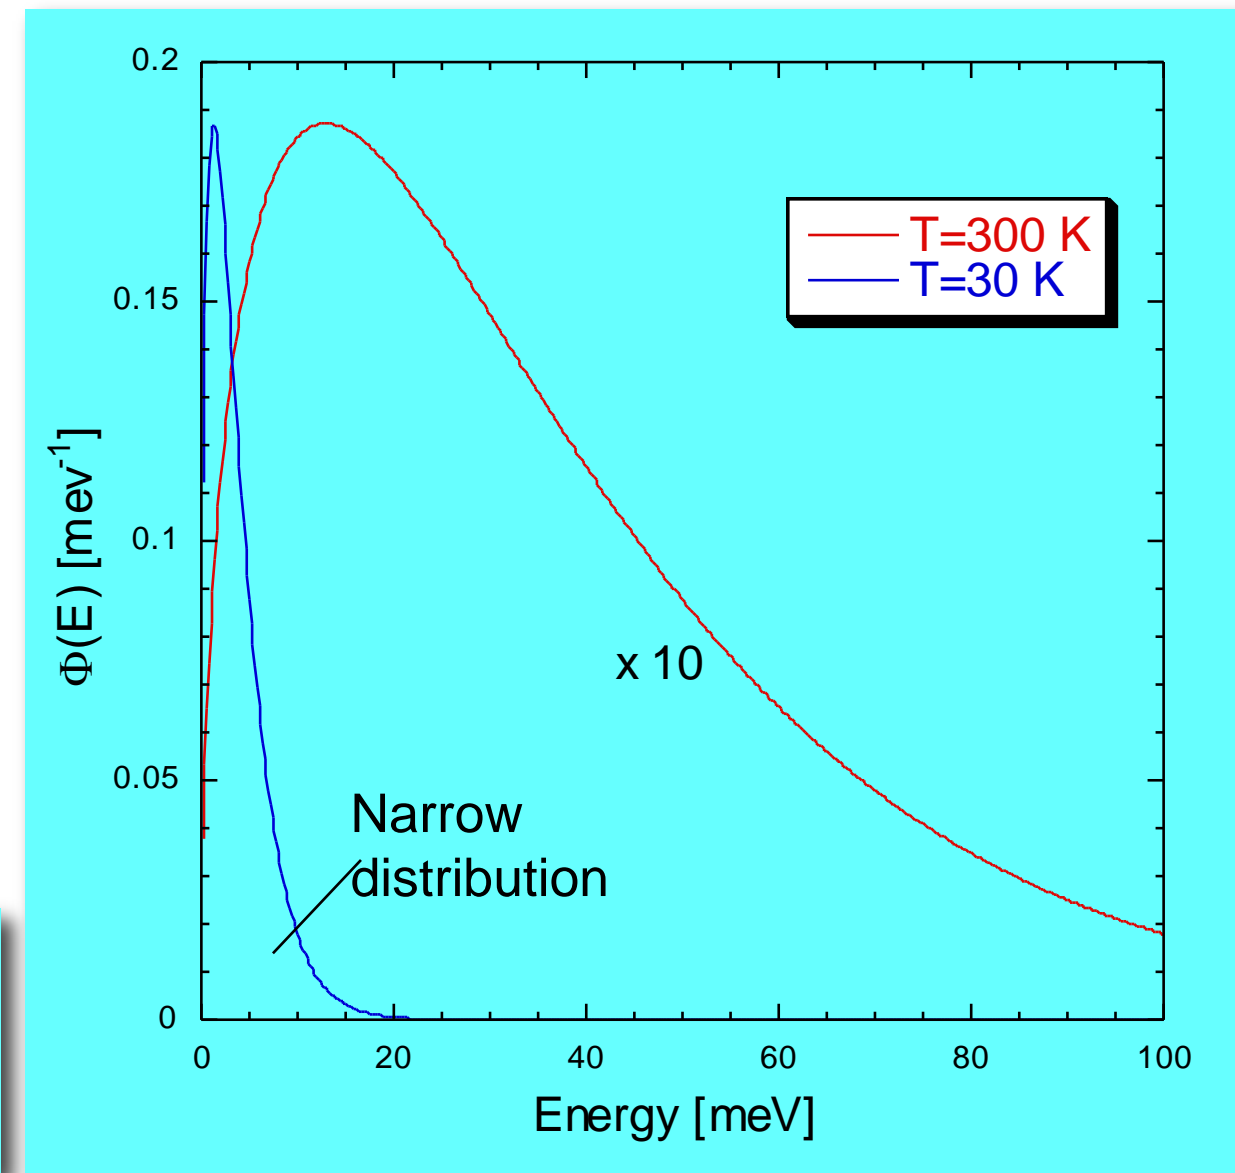

Moderation is essential

- Thermal region: Maxwell Boltzmann distribution

$$\Phi(E)dE = \Phi_{\text{thermal}} \frac{2}{\sqrt{\pi}} \frac{\sqrt{E}}{(k_b T)^{3/2}} \exp\left(-\frac{E}{k_b T}\right) dE$$

- Epithermal 1/E region
- Fast background
- Cold and Hot sources

UAl fuel element 93 % HEU

SNS Short pulse neutron spallation

An aerial photograph of a mountainous landscape. In the foreground, a river flows through a valley, surrounded by dense green forests. The middle ground shows rolling hills and valleys with patches of green fields and small settlements. In the background, a range of rugged, rocky mountains stretches across the horizon under a blue sky with scattered white clouds.

A short hike through the neutron landscape
I will try to cross as many vegetation zones as possible

Let us start at the bottom

- There are two ways to penetrate the depths of matter:
 - higher energies,
 - higher precision.
- Neutrons are relevant for the later:
 - neutron lifetime,
 - β -decay asymmetries,
 - the neutron's electric dipole moment,
 - neutrons as a gravitational probe.

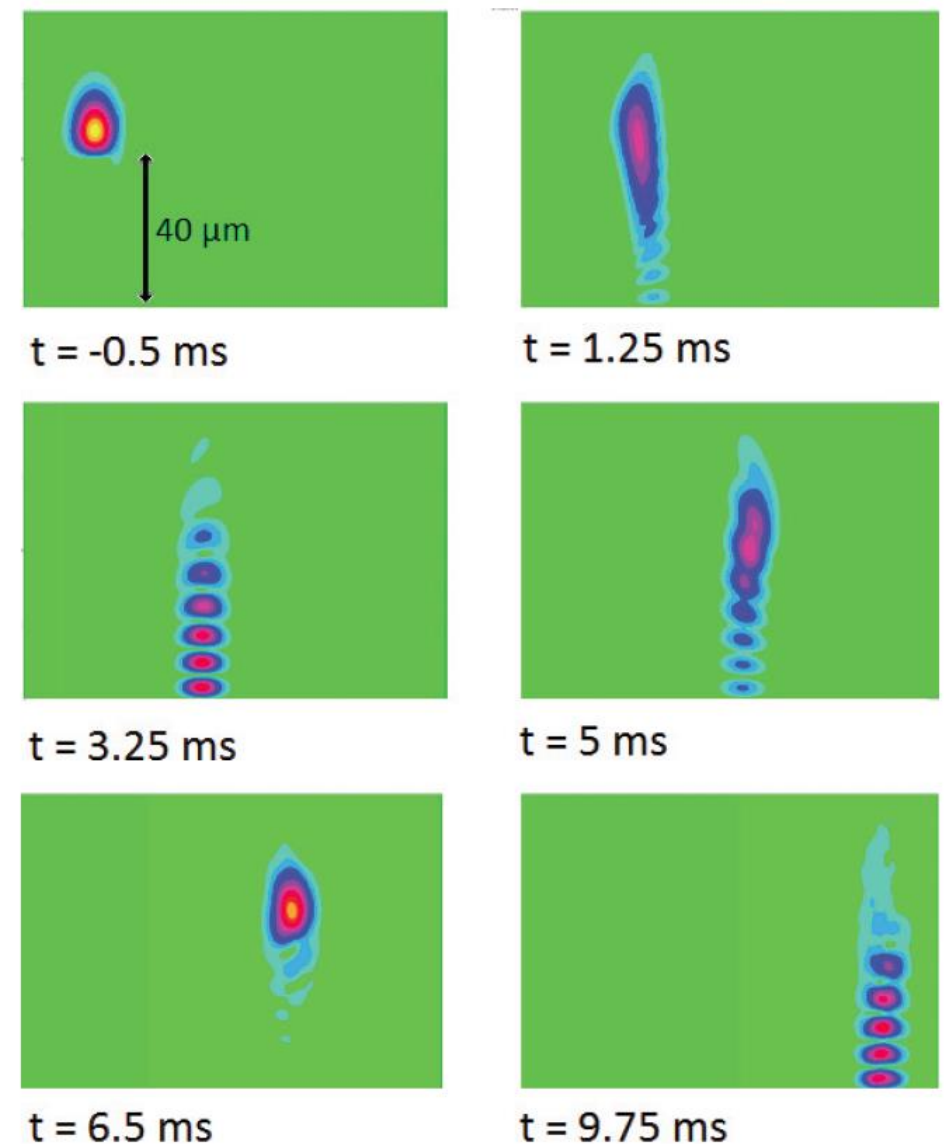

Gravitational forces at short distances

- Ultracold neutrons ($E < 100$ neV) are ideal quantum bouncers.
- As neutral elementary particles they do not stick to surfaces.

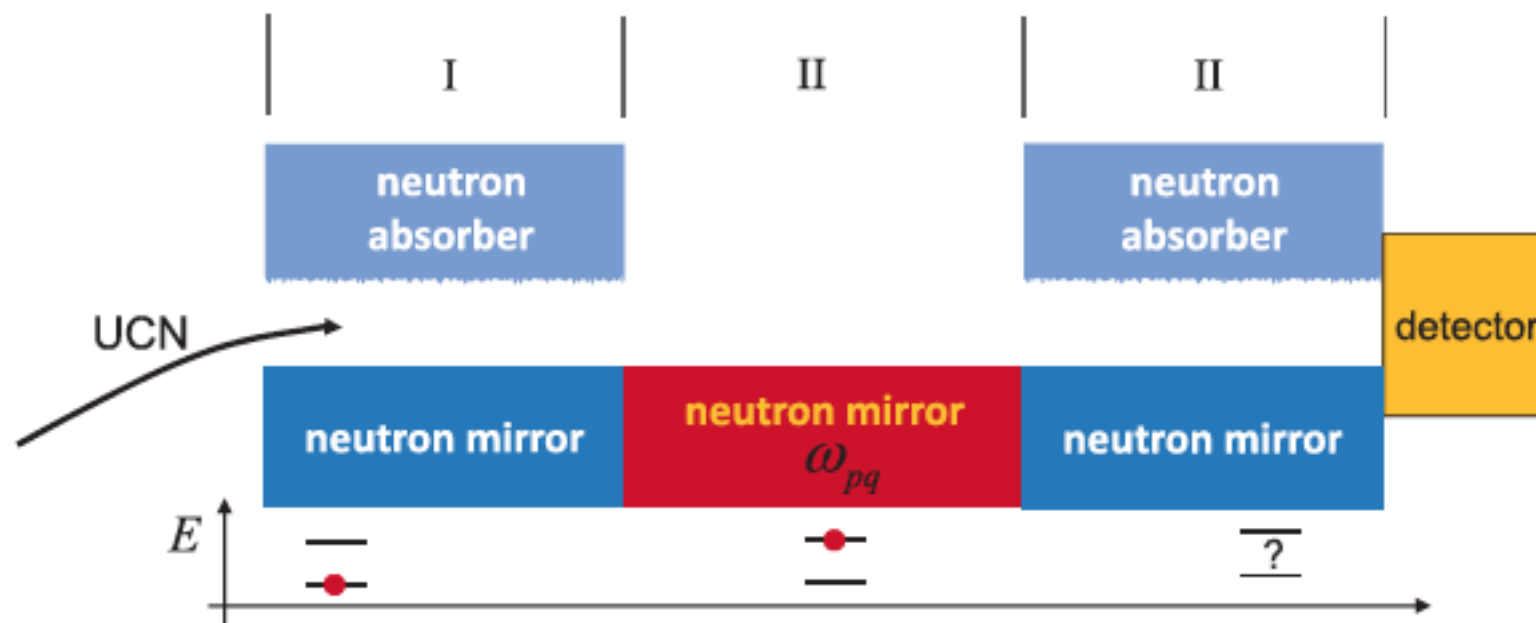

Jenke et al., Nature Physics 2011,
Abele und Rauch, New J. Phys. 2012

Quantum Bouncers

Precision measurements using resonance techniques

- Probing the gravitational potential on the μm scale with a precision of currently $\Delta E = 2 \times 10^{-14}$ eV.
- Essential experiments to check for non-Newtonian corrections to the gravitational field.

Resonance curve

From the fundamental interactions to the nuclei

Neutron capture is ubiquitous in the universe.
At a neutron source it can be used in a controlled way to probe nuclear matter.

Observing nuclear processes

- Producing neutron rich isotopes via capture.
- Spectroscopic analysis of decay processes with or without simultaneous (Z/A) identification of decay products.
- Essential input for
 - understanding nucleosynthesis,
 - designing transmutation of radioactive materials,
 - development of 4th generation reactors.
- Complementary to ion accelerators.

About 100 Terabyte of data await analysis by
40 research collaborations

Doping silicon for energy applications

15 tons of homogeneously n-doped silicon/year produced at FRM II ($\approx 10\%$ of world production)

Radioisotopes for medicine

Müller et al. J. Nuclear Medicine 2012

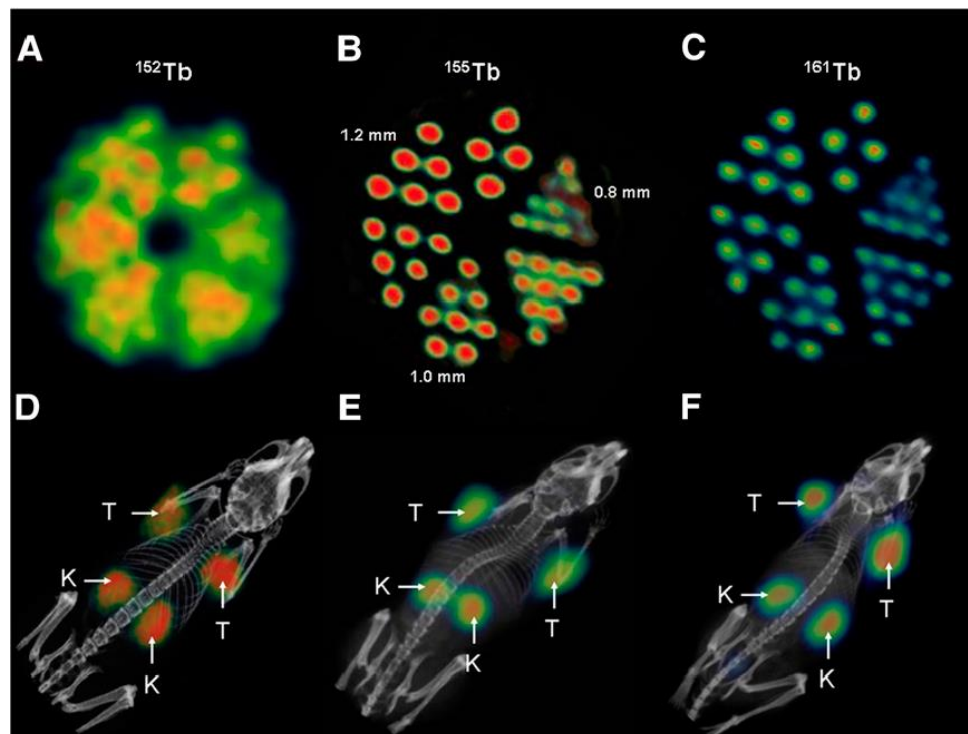

A collaboration between the Paul Scherrer Institute, CERN's ISOLDE facility, and the Institut Laue-Langevin

- Terbium radioisotopes possess excellent visualization and therapy efficiency.
- Terbium-161 is produced at FRM II or ILL for clinical purposes.

Tb-CM09

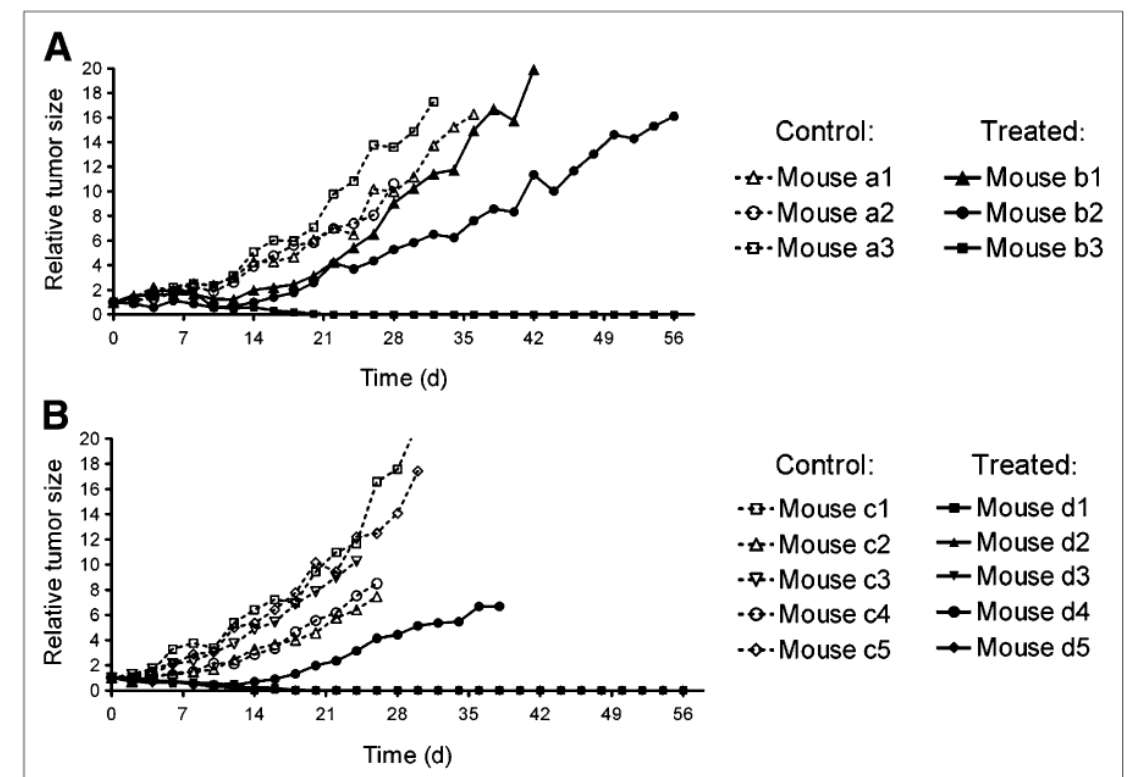

Diagnoses

Positron emission tomography

Single photon emission computed tomography

Therapy

From the nuclei to the solid

The Anderson-Higgs mechanism

- Gauge theories are the backbone of physics.
- This leads to broken symmetries and massless Nambu-Goldstone particles.
- The Anderson Higgs Mechanism couples the gauge bosons to Nambu-Goldstone particles and thus provides mass.
- Applications: Standard model of particle physics, superfluidity and superconductivity.

Higgs transition from a magnetic Coulomb liquid to a ferromagnet in $\text{Yb}_2\text{Ti}_2\text{O}_7$

- Magnetic frustration leads to defects that behave like a liquid of magnetic monopoles interacting via a Coulomb interaction.

Neutrons observe the ground state directly

Chang et al. Nature Communications 2012

Higgs transition from a magnetic Coulomb liquid to a ferromagnet in $\text{Yb}_2\text{Ti}_2\text{O}_7$

- Below 210 mK we find a ferromagnet with “anticipated” energy gap.
- This is analogous to creating a massive gauge particle.

The successful marriage of chemistry and magnetism

- Modern chemistry allows to specifically design molecular magnets.
 - Neutron spectroscopy on single crystals gives Fourier images of coherent spin excitations.
 - This allows to directly calculate the spin dynamics.
 - Potential for spintronics and quantum computing.
- Energy resolved scattering intensity

Barker et al. Nature Physics 2012

0.24 g von $\text{Cr}_8\text{F}_8[(\text{O}_2\text{CC}(\text{CD}_3)_3)_{16}]$

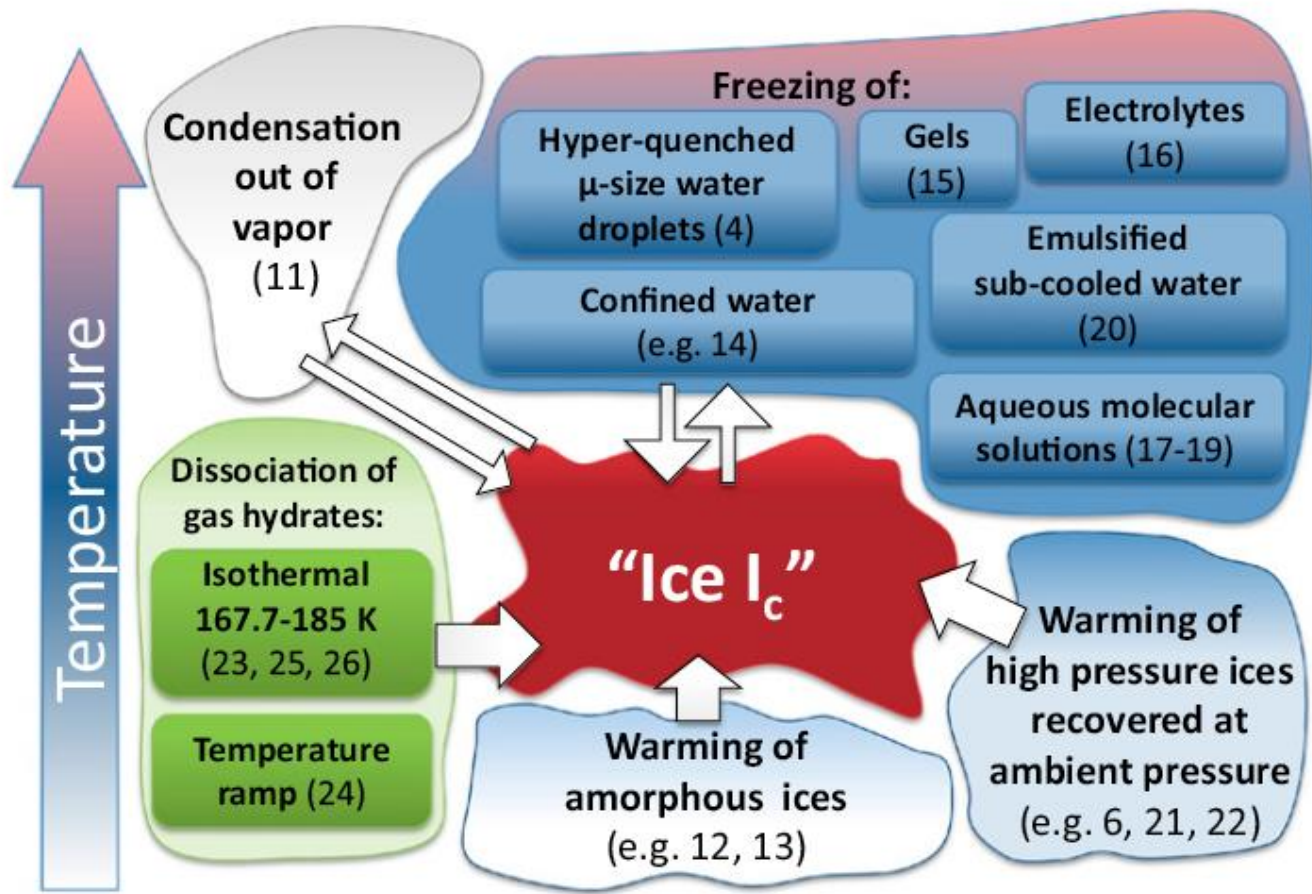

Molecular surgery

- Modern chemistry allows us performing physics in a nano-lab.

Transition is in principle forbidden.
Cages deformed?
Ferroelectric phase?

Neutrons investigate the crystalline state

Neutrons are particularly good when it comes to light elements like H, D and Li.

A contribution to climate models

- Exact monitoring of transition dynamics from cubic to hexagonal ice.
- Size and surface quality of crystallites extracted.
- Results constitute important input into models of
 - ice formation (including clathrates),
 - reflection of light in the atmosphere,
 - chemistry of the atmosphere.

W. Kuhs. et al, PNAS 2012

Following chemical processes in batteries

1) LiCoO_2 (1)
2) Cu (2)
3) Fe (3)
4) LiC_{12} (4)
5) LiC_6 (5)
6) Al (6)

- In-situ diffraction is possible.
- Cycling leads to creation of LiC_6 at the carbon anode.
- This loss of Li leads to a loss of capacitance.

Following the chemical changes in batteries: Images in real space.

- Commercial 18650 Li-Ion Batterie, reconstructed from neutron tomography.
- Different colors symbolize the Li concentration.

Remaining at macroscopic length scales: Strain and stress in materials

- Efficiency often comes at the price of more severe operating conditions.
- This leads to stress in the materials.
- Neutrons provide direct access to strain with ideal gauge volume and deep penetration.

An Example:

Fatigue crack growth in a weld.

Neutrons

gauge volume

- In total the weld was subjected to over 100,000 fatigue cycles.
- The figure shows the variation of residual stress in the weld with crack length c .
- Linear elastic fracture mechanics are valid for the assessment of fatigue performance.

Going a further step up: The supramolecular level

Lipid rafts are essential for the functions of the cell membrane.

How are these rafts stabilized?

Spingomyelin (a) and Cholesterol (b)

The supramolecular level: membranes

Structural correlation are observed between glycosphingolipis and cholesterol creating an asymmetric structural unit across the membrane that may influence local structural properties of rafts.

Rondelli et al. BBA (2012), Fragneto

Ganglioside GM1 penetrates into the outer layer of the free floating membrane.

Cholesterol migrates to the opposite leaflet.

Biology at the service of medicine.

Transthyretin (**TTR**) is a serum and cerebrospinal fluid carrier of the thyroid hormone thyroxine (T4) and retinol binding protein bound to retinol.

T. Forsyth et al., unpublished

- Highly symmetric center of homo tetramer.
- The side chains of the four Ser-117 residues create a barrier between the two docking sites of the hormone.
- Neutrons show differences in the orientation of the binding of the G-deuterium in the A- and B-chains in addition to an isolated water molecule.

Biology at the service of medicine.

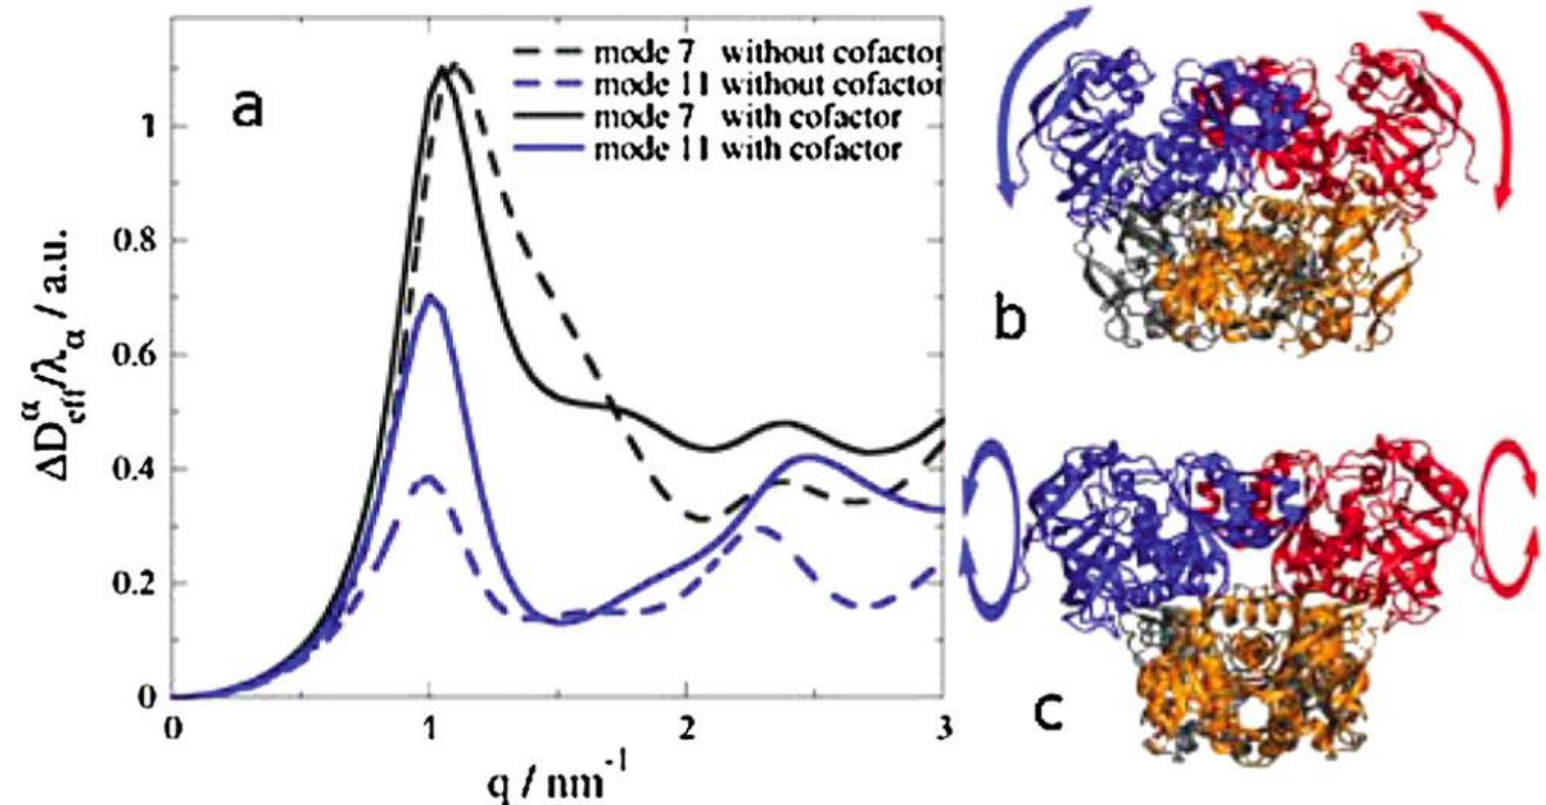

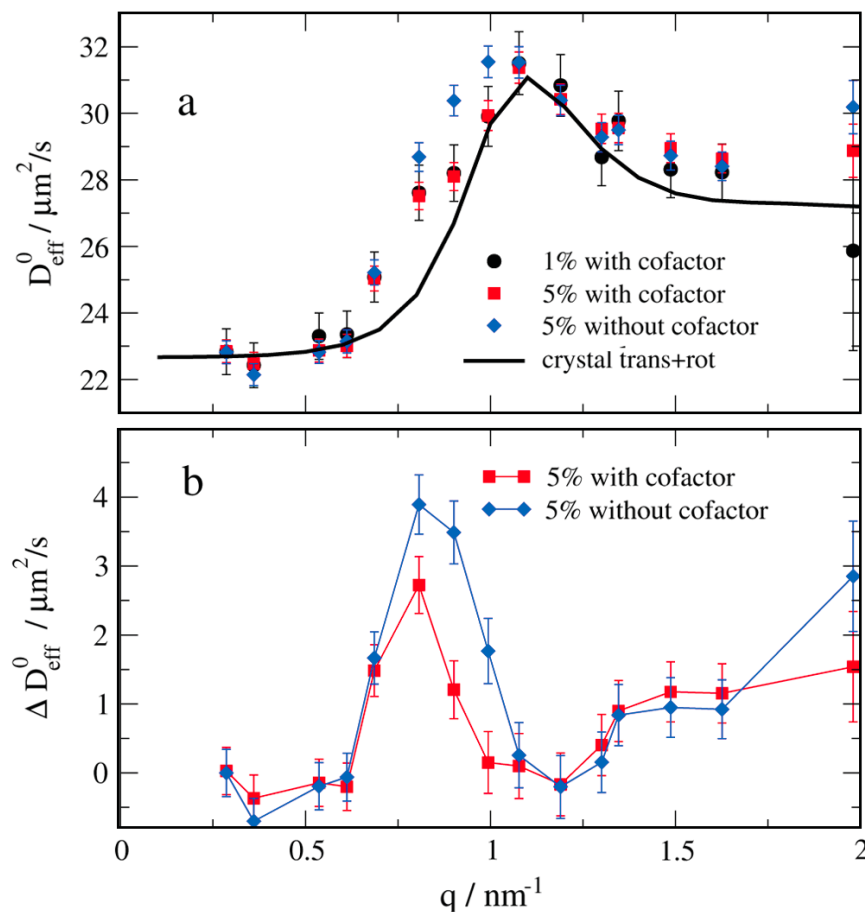

- **Amyloids** are insoluble fibrous [protein](#) aggregates.
- Abnormal accumulation of amyloid fibrils in organs may lead to **amyloidosis**, and may play a role in various neurodegenerative [disorders](#).

Biological function equally is exploiting fast dynamics

Biehl, et al. Physical Review Letters, 101(13):138102 (4 pp.), 2008.
Correlated Interdomain Motion in Alcohol Dehydrogenase

I hope you enjoyed the walk!
