Reference documents prepared by the LC community:

- Tesla TDR (2001) **part III** on physics
- 2004 **Report** on the complementarity of LC and LHC
- CLIC **physics report**
- ILC Reference Design Report (2007): **physics** and **detectors**
- Letter Of Intent of the ILC experiments (2009) **SiD** and **ILD**
- Conceptual Design Report (2012) of the **CLIC detectors**
- This summer (june 2013): **ILC TDR**
- Includes: **Detailed Baseline Design** for the ILC experiments

Future linear e^+e^- colliders

Accelerator R&D around the globe. Non-exhaustive list of test facilities:

ATF@KEK, nm size, low emittance beams

CTF3@CERN, drive beam

CESR/IT@Cornell (electron cloud)

XFEL@DESY

Future linear e^+e^- colliders

Superconducting RF cavities are in the industrialization phase and routinely reach gradients well over 30 MV/m.

RF technology exists for a low-energy machine ($\sqrt{s} \sim 250\text{-}500$ GeV)

ILC is shovel-ready!

Niobium Superconducting Cavities
1.3 GHz 9-Cell ILC/TESLA

Niobium in stock for quick delivery!

\$49,999*

NIOWAVE
Accelerating Your Particles
www.niowaveinc.com
sales@niowaveinc.com
517.999.3475

*Entry level niobium cavity delivered in 3 months (other options available).

Let us help you customize the exact niobium structure you need from 28 MHz to 3.9 GHz and beyond.

Contact us to discuss your needs

Future linear e^+e^- colliders

Higher gradient (~ 100 MV/m) can be achieved using drive beam concept.

R&D for $\sqrt{s} \sim 1-3$ TeV \rightarrow CLIC to open up the multi-TeV regime.

The e^+e^- precision physics programme

The physics programme of the LC (ILC and/or CLIC) envisages runs at several center-of-mass energies:

91 GeV *GigaZ* (*optional*) high-lumi run at the Z-pole

- ultra-precise measurements of electroweak observables

250/350 GeV *Higgs factory* study of $e^+e^- \rightarrow ZH$ process using recoil method

- Higgs couplings to Z and W, g, c, b, τ

345-355 GeV *top threshold scan*

- Precise top quark mass (width, α_s and top Yukawa coupling)

500 GeV (*nominal ILC energy*)

- Precise electroweak top couplings

For a detailed physics case, see Frank Simon's presentation

1 TeV (*ILC energy upgrade*)

- *Higgs self-coupling*

1.5 - 3 TeV (*CLIC high-energy programme*)

Leptons vs. hadrons

Colliding (composite) hadrons is different from colliding (elementary) leptons in several important ways

At lepton colliders:

- **Production rates are precisely calculable:**
 - *5% uncertainty on $t\bar{t}$ cross-section at LHC is a milestone, per mil level is feasible at ILC → precise calibration of luminosity*
- **Every GeV delivered to the projectile is used:**
 - *a 2 TeV hadron collider may not be enough to find a 126 GeV particle, a 250 GeV lepton collider certainly is!*
- **The initial state is precisely controlled:**
 - *total energy sums of to $2 E_b$ → recoil mass analysis, energy scales polarization can be controlled (at linear collider)*
- **Production rates are democratic:**
 - *events producing Higgs, top and major backgrounds are ~ equally likely. At hadron colliders we have to work through many orders of magnitude of QCD to reach rare processes*
- **Non-collision events are approximately empty:**
 - *no pile-up, relaxed read-out times, less radiation damage*

LC detectors

LC environment and detector R&D allow for a big leap in performance

- Well-defined initial state (CM energy, polarization)
- Signal and bkg x-sections of similar magnitude
- Triggerless read-out
- Background confined to innermost detectors

Particle Flow: highly granular calorimetry inside a large 3.5-5 Tesla solenoid allows to follow every single visible particle produced in the collisions from the cradle to the grave → best possible estimate of the jet energy: $\Delta E/E \sim 3-5\%$

Transparent and precise tracking/vertexing:

$$\Delta(1/p_T) \sim 10^{-5} \text{ GeV}^{-1}$$

$$\Delta(d_0) \sim 5 \oplus 10-20 / (p \sin^{3/2} \theta)$$

Detailed Geant4 model and sophisticated reconstruction software allow realistic estimates of performance

Vertex detector

Vertex detector

Reconstruct primary and secondary vertices,
flavour tagging, bottom/charm separation

Large polar angle coverage

Unprecedented performance:

$$\sigma(d_0) < 5 \oplus 10/(p \sin^{3/2} \theta)$$

Stringent requirements

Precision ($20 \times 20 \mu\text{m}^2$)

Read-out speed (25/100 μs)

Material: 0.1...% / layer

See Frank Simon's talk

| | a (μm) | b ($\mu\text{m GeV}$) |
|-----|---------------------|-------------------------|
| LEP | 25 | 70 |
| SLD | 8 | 33 |
| LHC | 12 | 70 |
| ILC | 5 | 10 |

**Strongly reduce the multiple
Coulomb scattering term**
(0.1 % X_0 / layer $\sim 100 \mu\text{m Si}$)

*No end-cap drawn, but
coverage down to 6 degrees*

Environment

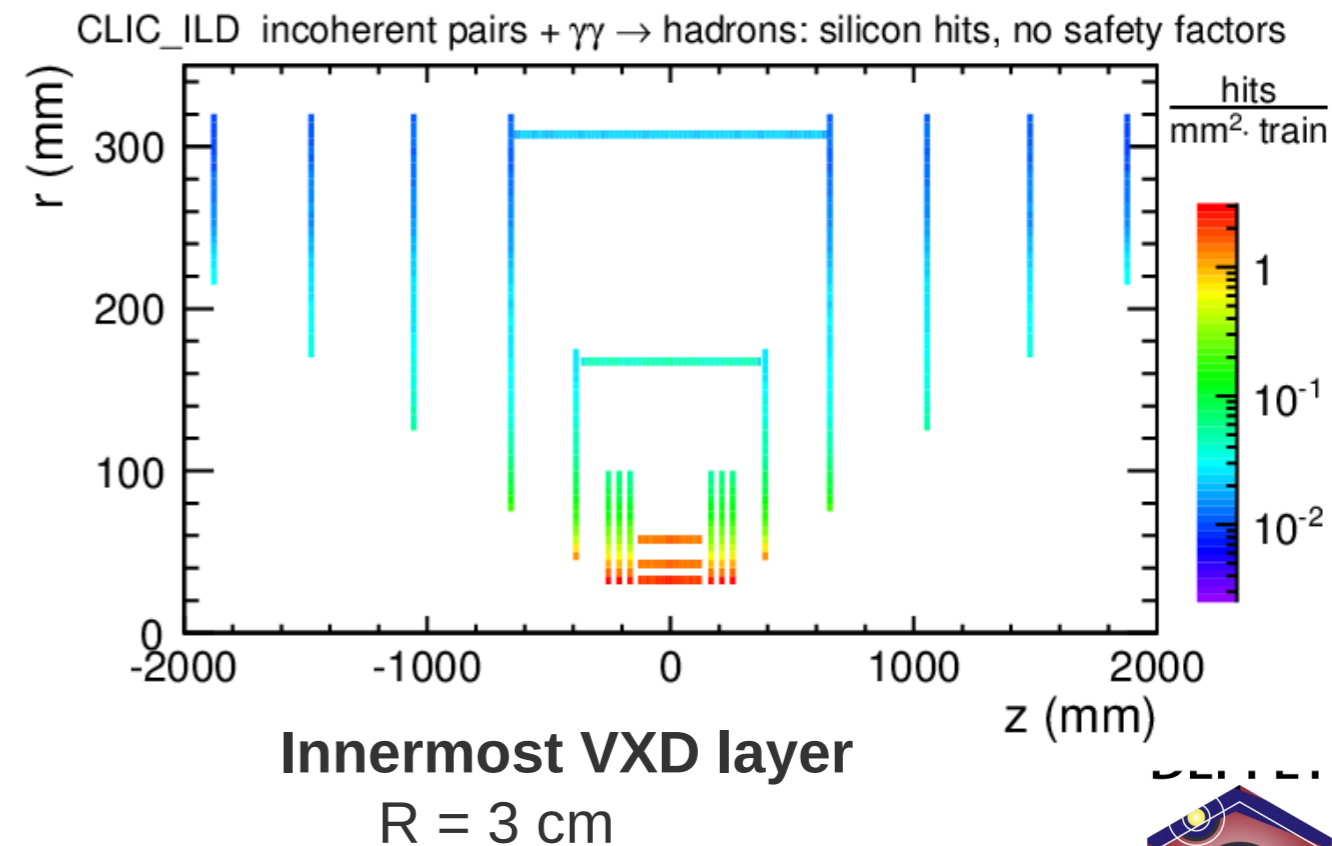

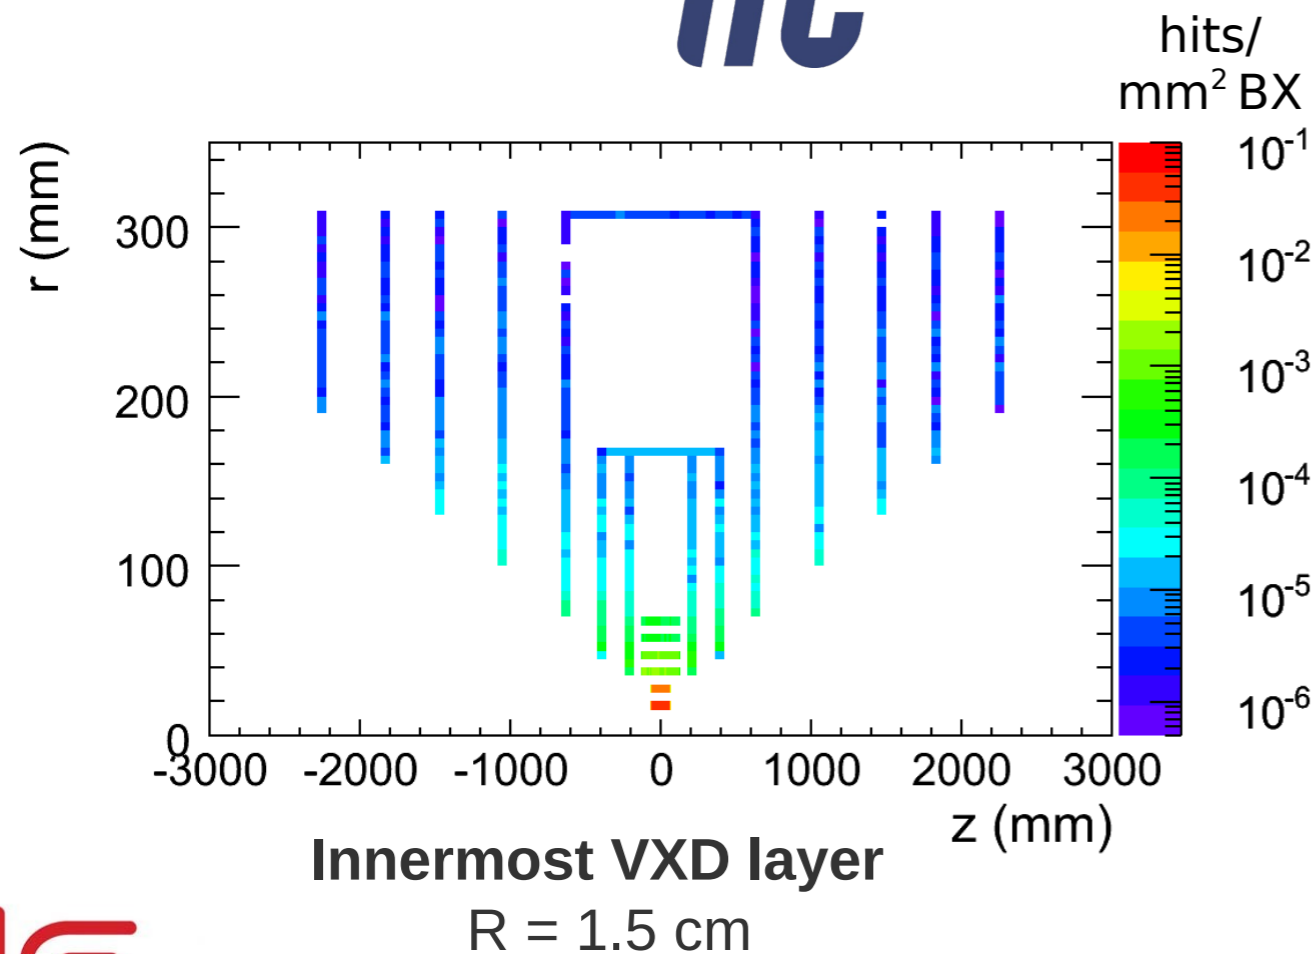

Background levels in innermost detectors drives read-out speed requirement.

→ large uncertainties and strong dependence on the machine design

Rates are much reduced during initial low-energy phase

CLIC has ultra-fast bunch train structure: 312 BX in 150 ns

→ requires 10 ns time stamping for all sub-systems

Detector concepts

ILD (see **DBD**)

Candidate technologies:

(mature & pursued in ILD)

- CMOS MAPs (Strasbourg)
- FPCCD (KEK)
- DEPFET

One-page description in DBD

Several alternatives

A number of alternative technologies are under study which could feature the required high granularity and low material budget. Developments undertaken for the high energy run of the ILC, in particular high-resistivity substrate CMOS sensors and to multi-tier 3D pixel sensors.

SiD (see **DBD**)

Pushes for 3D integration
single BX time stamping

Fall-back scenario:

DEPFET, MAPs, FPCCDs

CLIC (see **CDR**)

Pushes hybrid solution
(TimePix)
10 ns time stamping
Prohibitive for most

(alternative with timing fast timing layers interleaved with precise layers that integrate 150 ns bunch train – 20 ms to process frame)

Belle II synergy

| | <i>ILC</i> | <i>Belle-II</i> |
|-----------------|--|---|
| occupancy | 0.13 hits/ $\mu\text{m}^2/\text{s}$ | 0.4 hits/ $\mu\text{m}^2/\text{s}$ |
| radiation | < 100 krad/year | > 1Mrad/year |
| | 10^{11} 1 MeV n_{eq} /year | $2 \cdot 10^{12}$ 1 MeV n_{eq} /year |
| Duty cycle | 1/200 | 1 |
| Frame time | 25-100 μs (10 ns @ CLIC) | 20 μs |
| Momentum range | All momenta | Low momentum (< 1 GeV) |
| Acceptance | 6°-174° | 17°-150° |
| Resolution | Excellent 3-5 μm (pixel size = 20 x 20 μm^2) | Moderate (pixel size = 50 x 75 μm^2) |
| Material budget | 0.12 % X_0 /layer | 0.15 % X_0 /layer |

Belle-II presents a more severe challenge than the ILC in several aspects.

Belle II synergy

For a status report of the DEPFET project for Belle II see Carlos Lacasta's talk

From concept to system, from prototypes to complete detector

- design and produce every component
- hands-on experience with mechanical properties of thin sensors
- study (air) cooling

Progress in read-out and steering ASICs

Operating the complete chain

DEPFET LC prospects

AROUND THE WORLD

DEPFET active pixel detectors for the linear collider

Marcel Vos reports on behalf of the collaboration

[Share](#) | [Facebook](#) | [Twitter](#) | [Email](#) | [Print](#)

24 January 2013

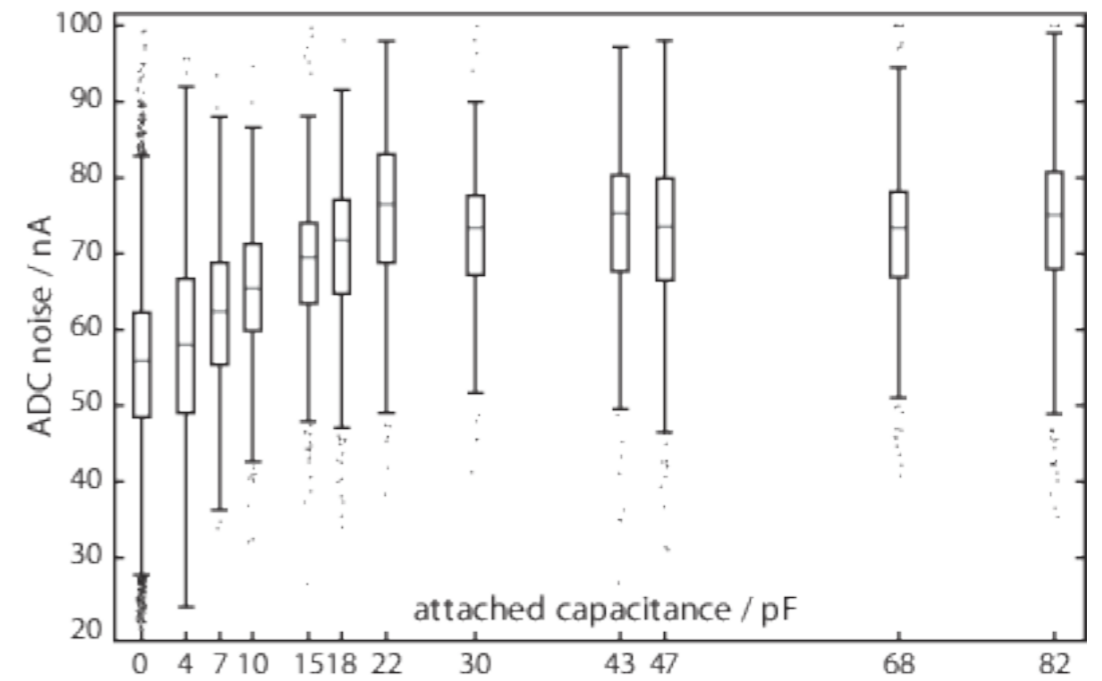

Solid-state devices for charged particle tracking proved their value in high energy physics in the most internal layers of the experiments of the Large Electron Positron Collider LEP at CERN, where they provided precise information on the production vertex of charged particles. These silicon micro-strip detectors consisted of a thin reverse-biased pn -junction segmented in narrow strips, each of which was read-out by an amplifier and analog-to-digital converter on a read-out ASIC. After a rapid evolution fueled

ASIC performance

Can now base LC prospects on measurements

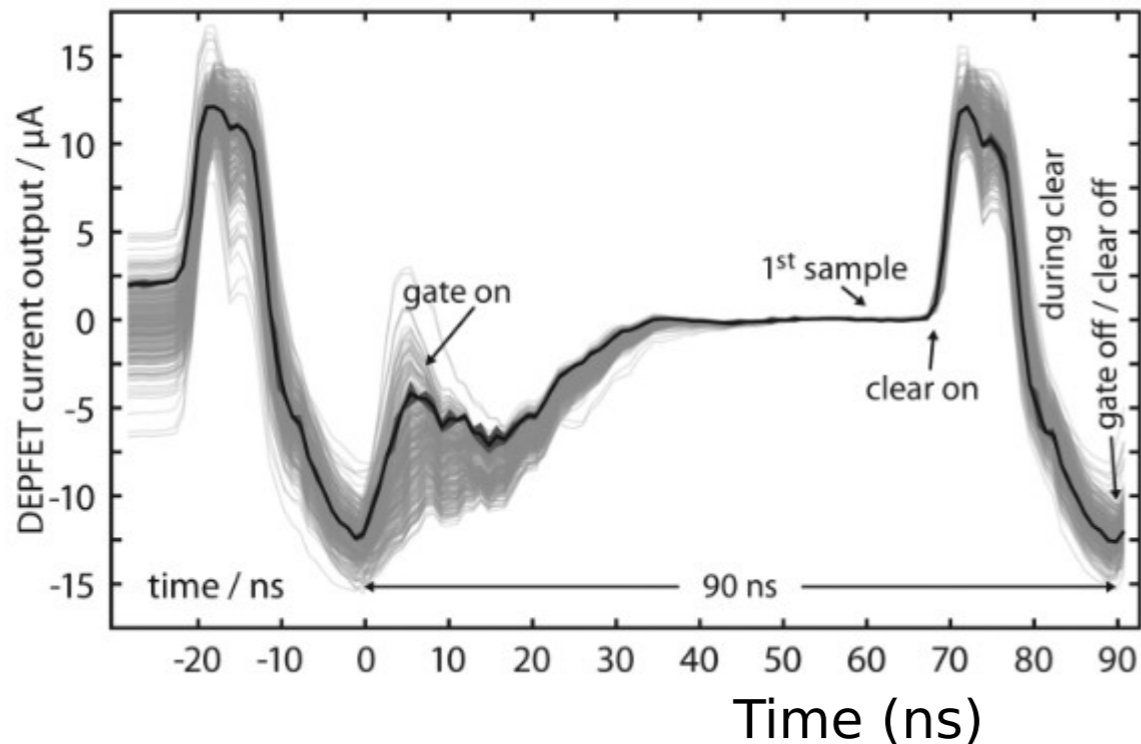

Noise of the FE chip (DCD) versus capacitive load

Clear pulse from Switcher

DEPFET @ LC - barrel

Read-out speed: current state-of-the-art allows for a row rate of 1/100 ns. Room for improvement.

VXD0 → 12.5cm long barrel layer with read-out ASICs on both ends.

Pixel size:

Center ($|z| < 1$) → $25 \times 25 \mu\text{m}^2$

$1 < |z| < 2$ cm → $25 \times 50 \mu\text{m}^2$

$|z| > 2$ cm → $25 \times 100 \mu\text{m}^2$

Column depth: 1025 pixels/half-ladder

Multiplexing: 2 (4) rows sampled in //

Row rate: 1/80 ns

Frame time: 40 μs (20 μs)

DEPFET @ LC disks

- LC detector concepts require pixelated disks
 - vertex detector end-cap in SiD, Forward Tracking Disks in ILD
 - adapt DEPFET all-Si “ladder” design to “petal” geometry

- Working on fully engineered design + mock-up
- Hoping to learn:

Sensor: feasibility of layout with variable pitch & length

Ancillary: length of switcher lines, load on DCD...

Mechanics: self-supporting frame

Cooling: air flow through disks

Physics: assess performance of this design

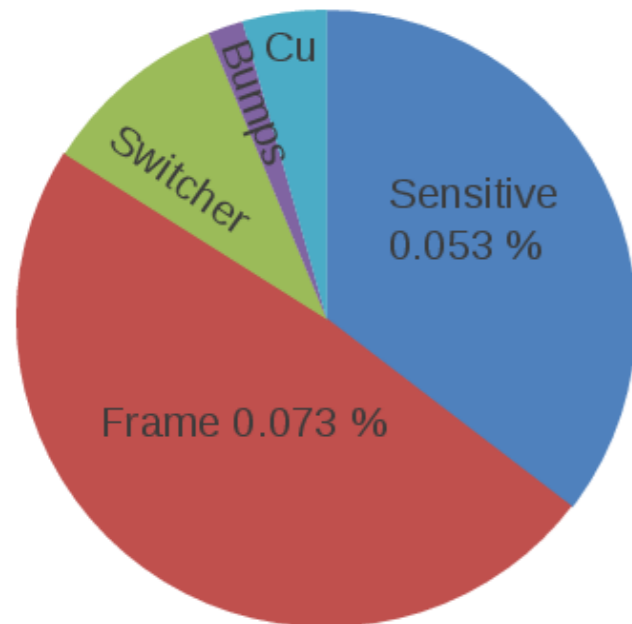

Material budget

Integrate!

- Amplification stage in sensor
- Support structure in sensor
- Signal and power lines on sensor
- Electronics on sensors

| | |
|---------------------|--------------------------------|
| Sensitive | 0.053 % X_0 |
| Frame | 0.073 % X_0 |
| Switcher | 0.015 % X_0 |
| Cu layer | 0.007 % X_0 |
| Bumps | 0.003 % X_0 |
| Total ladder | 0.15 % X_0 |

Material budget close to LC goal!!!

Tracker Material Budget

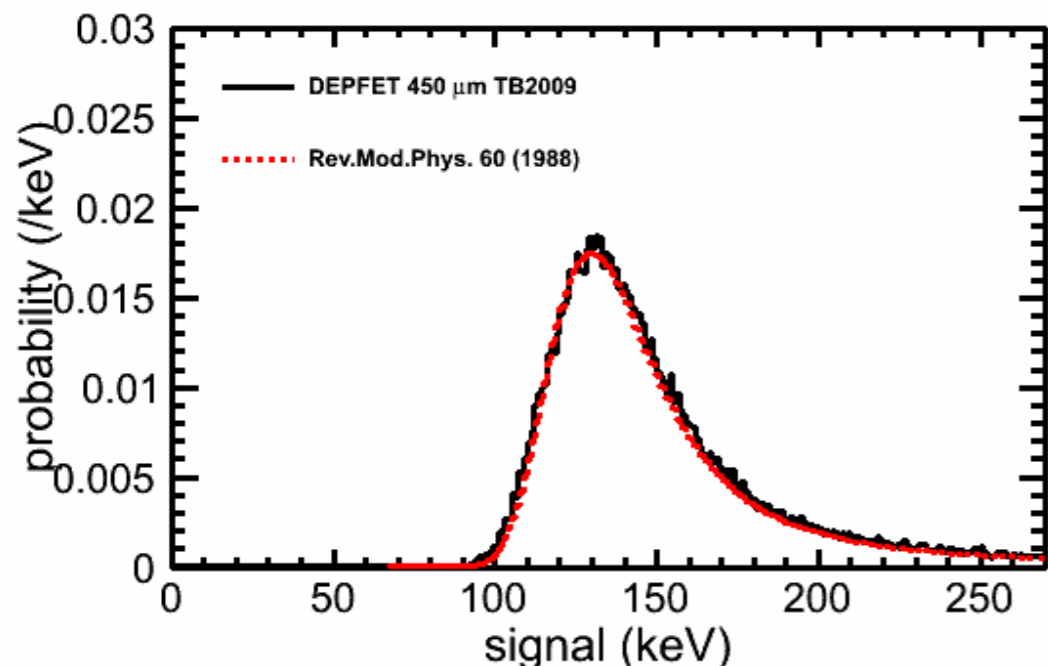

Big leap wrt to LHC...

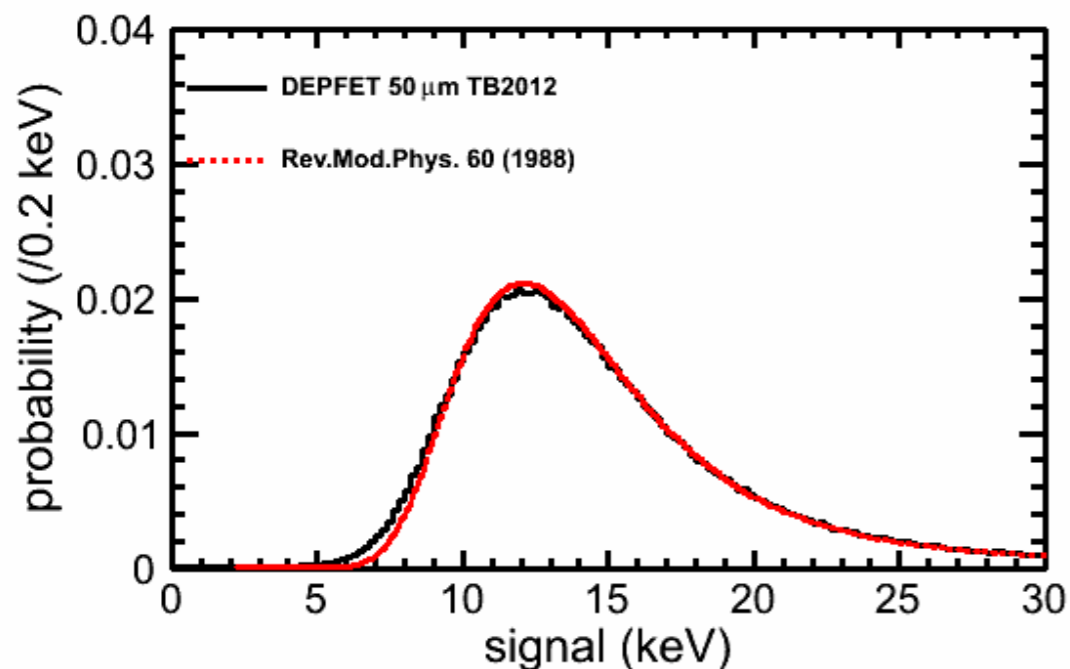

Admittedly not a fair comparison

Test beam measurements

450 μm thick prototype
with 20x20 μm² pixels
Slow (CURO) read-out
S/N ratio = 130-200

50 μm thick prototype
With 50x75 μm² pitch
Close to final (DCDB) read-out
S/N ratio = 20-40

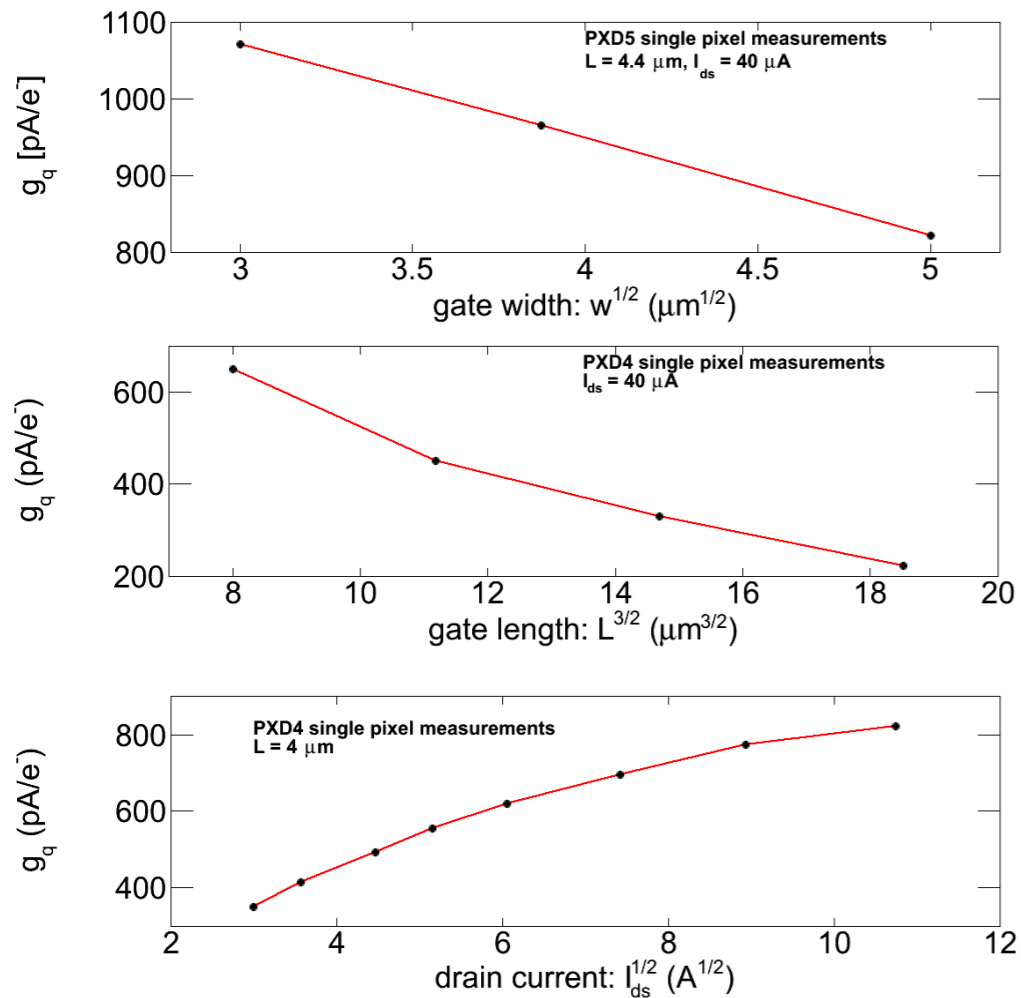

**A major milestone
for the Belle II and
LC projects**

Excellent agreement with straggling model by H. Bichsel
up to several times the Most Probable Signal
Width of distribution due to “Landau” fluctuations
correctly predicted

Internal amplification

A key DEPFET parameter:
 Larger $g_q \rightarrow$ higher S/N
 \rightarrow thinner sensor

4 years of gain measurements on many different sensor designs

Spatial resolution – perp. incidence

450 μm thick DEPFET sensors have registered a resolution for perpendicularly incident minimum ionizing particles (120 GeV pions) of approximately **1 μm**

Questions: *Is that what we would expect?*
What should we do to do better still?

Theory Answer: $\sigma \propto \frac{p}{S/N}$ (constant depends on charge sharing details)
Assuming signal distribution is a good measure of particle position

Image of a δ electron captured in a DEPFET beam test

Artificially worsen the S/N ratio by smearing the signal

The spatial resolution “saturates” for very large S/N ratio, at least in part due to δ -electrons

“Landau” fluctuations

Toy model to propagate fluctuations to position measurement
M. Boronat (Preliminary)

thin sensors (d=50 μm) $\sigma/p \sim 10\%$

thick sensors (d=300-500 μm) $\sigma/p \sim 7\%$

Ideal detector ($S \mu l$)

Smearing TB data on 50 μm DEPFET

Fluctuations in signal deposition per unit length of the particle trajectory in silicon limit the resolution.

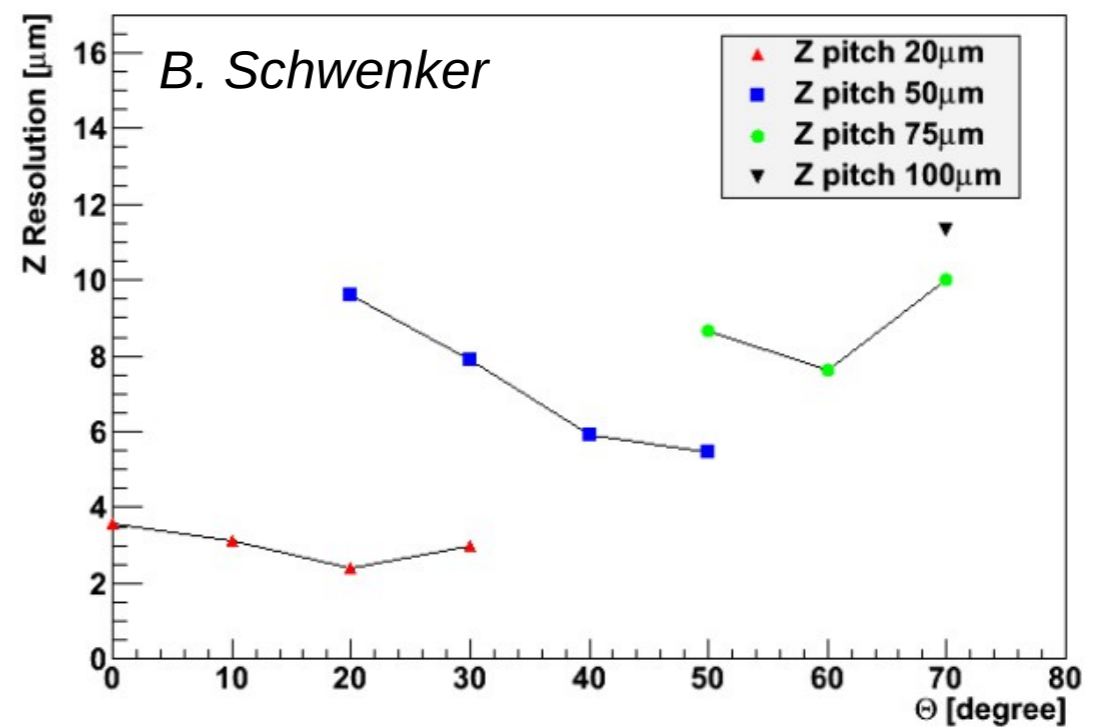

Spatial resolution

Digitizer predictions for LC
DEPFET spatial resolution

$r\phi$ -resolution varies between
2.3 - 3.5 μm
(ILD spec. 2.8 μm , SiD 5 μm)

z-resolution is similar for $\theta < 45^\circ$,
but a degradation for shallow
tracks seems inevitable

DEPFET @ LC: conclusions

The “next big machine” might become a reality in Japan

DEPFET remains a strong candidate for LC vertex detector

- benefit from progress building the Belle II system
 - proof-of-principle for thin sensors
 - development of complete read-out chain
 - measurements validate cooling and mechanical concept
- LC prototypes can cope with requirements
 - small-pixel: $20 \times 20 \mu\text{m}^2$
 - 2-4 μm spatial resolution
 - read-out speed: 40 μs /frame for ILD layer 1
 - ladder material $\sim 0.15\% X_0$, close to LC specification
- Learnt something about limitations of spatial resolution along the way
- next generation of LC prototypes expected soon
- petal design for disks underway
